But in quiet times he would dissect out with microscopic exactness every atom of devitalized tissue. He reads accurately not only the wound but the patient, not only the patient but the military situation, not only the military situation but the condition of the infecting soil, the state of transport, his surgical assistance and the type of nursing care—that is, he weighs accurately his chances for success. Therefore the army medical service and the wounded man pin their hope and their faith first, last and always to the one agency of wound treatment that in civilian surgery emerged clearly from the confusion of the hysterical period, is emerging clearly from the confusion of the four years of military surgery—the sane, sound surgeon."

BRITISH MEDICAL PLANNING

Further light on the attitude of the British Medical Association to the now famous Interim Report of the Medical Planning Commission is given by the votes on two resolutions that were brought up in the discussion of this report at the annual representative meeting of the British Medical Association.¹ A motion with regard to medical service "that provision, of whatever character, should be made by the government for the whole community" was, after considerable discussion, adopted by the very close vote of 94 for and 92 against. The effect of this was also immediately modified by the adoption of a "rider" providing that "the patient should have the right to contract out and the doctor the right to charge fees for attendance to patients not on his list." A motion "that the basis for the coordination and integration of health services should be the establishment of a whole time salaried government service" was defeated by a vote of 20 to 177. This would apparently indicate an overwhelming opposition of the medical profession to a comprehensive state medical service.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

CIVILIAN DEFENSE

PROTECTION FOR INDUSTRIAL PLANTS

The Office of Civilian Defense, Washington D C, has published a pamphlet entitled 'Passive Protection for Industrial Plants' in which in the section on 'Medical Services' it is recommended that each industrial plant in addition to providing its own medical staff and first aid equipment should plan in collaboration with the chief of the Emergency Medical Services of the locality for (1) services of ambulances and Emergency Medical Field Units when needed, (2) available beds at one or more hospitals to which the severe casualties may be transported (3) the establishment of a casualty station of the Emergency Medical Service within a short distance of the plant and (4) obtaining the services of Emergency Medical Field Units if needed to supplement the plant medical service during an emergency.

If the industrial plant is miles from the hospital, the casualty station should be larger than the average and must be equipped at least with the emergency medical supplies in medical division bulletin No 2, equipment lists 1 and 2. The primary purpose of the casualty station is to care for the slightly injured and thus protect the hospitals from caring for minor casualties. It will serve also as a center for the storage of medical supplies and for the dispatch of medical service to different parts of the plant. The first aid posts are established at the time of emergency as near as possible to where the casualties are being extricated.

All general hospitals in the community are included in the Emergency Medical Service, and the community control center will designate the hospital to which casualties from the industrial plant may be sent. Trained stretcher bearer teams should be organized among the employees by the medical director each

team comprising four persons. Five per cent of the plant personnel should be trained in these duties in order to have stretcher teams on call during each shift and in each wing of the plant. The minimum number of stretchers recommended according to this pamphlet is in plants having from one to ninety-nine employees—one stretcher for each twenty-five persons, and in plants having from one hundred to four hundred and ninety-nine employees, one stretcher for each fifty persons (minimum of four).

It will be advisable for industrial plants to provide improvised ambulances for their use in the event of an emergency. All requests for ambulance service from the community should be made to the control center of the Citizens Defense Corps.

CHANGE IN TERMINOLOGY OF CIVILIAN DEFENSE DIRECTIVES

In view of the revised system of directives of the Office of Civilian Defense, Washington D C established by operations letter 83 the previous series of Medical Division memorandum will end with No 18. The Medical Division Memoranda series will be continued as Circular, Medical Series and will be numbered consecutively, beginning with No 19 dated Nov 10, 1942, in which the foregoing information is contained.

CIVILIAN DEFENSE PERSONALS

Dr M V Ziegler, formerly director of Division No 3 of the U S Public Health Service, has left Chicago to become regional medical director of the Office of Civilian Defense in Baltimore.

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

According to DNB of September 17, doctors from twenty-five countries have assembled in Innsbruck for a conference of foreign and German doctors. In addition to the friendly European countries Japan, China, India and Thailand are represented. The conference, which is under the patronage of Gauleiter Hofer, has been jointly arranged by the foreign department of the reich health directorate and the foreign department of the Union of University Teachers. The discussions are concerned above all with the question of preventive medicine, cancer research and the fight against cancer, population policy and tuberculosis.

Reich leader of university teachers Dr Schultze declared that this conference of German and foreign doctors lasting for a week in the midst of war provides proof of Germany's strength in the scientific and cultural spheres and shows how a European way of thinking and feeling is increasingly taking shape. Reich health leader Dr Conti in the chief speech of the day outlined the health situation of the German people. A people can prosper only if it has sufficient space and sufficient soil for cultivation; otherwise a pathologic development is inevitable. We Germans were today fighting for the soil which we need to live.

Dr Conti dwelt with emphasis on the idea of racial welfare (rassenpflege), which has often led to misconceptions and even to malicious interpretations abroad. The idea of the value of blood is not a factor which separates nations but one which reconciles them by the recognition of natural differences.

According to NDZ of September 16, the reich minister of the interior has issued a decree aiming to provide adequate

dental services for the population of the reich. The decree authorizes the reich leader of dentists to direct dentists to settle in districts where there is no provision for the dental needs of the population. On the other hand a dentist may not close his practice without having previously obtained permission. The minister of the interior has been authorized to reform the training of dentists so as to make it uniform throughout the reich.

According to NDZ of September 22 in order to unify the measure of preventive and protective care for infants and toddlers in all advice bureaus for mother and child, infant welfare centers and similar institutions Dr Conti has made it compulsory to keep health record sheets for the infant and toddler which will be uniform for the whole reich. All state, communal and party authorities must in future use those health record sheets. These will register the child's development, cases of illness, condition of the teeth, prophylactic treatment for rickets and other items. The health record sheet is protected by the pledge of secrecy customary among the medical profession, which is extended to all those engaged in preventive and protective care of infants. The sheet is to be kept in the health office or in the advice bureau of the health office or the NSV of the district in which the child resides. As the child grows older the health record sheet for infants and toddlers will serve as a basis for the new health record sheet for juveniles, which it resembles.

NDZ of September 21 publishes extracts from an article by Oberstabsarzt Dr Ruhe in the periodical *Gesundheitsführung* dealing with the special measures of medical care, retraining for civilian life and the like for seriously wounded soldiers.

There are special military hospitals for blinded soldiers and for men with brain injuries where the men are given a certain amount of training under medical supervision to fit them once more for civilian occupations.

Kraiker Zeitung of September 6 reports that the German minister of health, Dr. Conti, accompanied by Oberfeldarzt Dr. Bernhardt, arrived in Warsaw on September 5 for a short visit. He spoke with medical personnel and military surgeons.

According to NDZ of September 12, virulent epidemics no longer threaten the life of the nation, even in times of war. Tuberculosis, however, has by no means been deprived of its terrors. The first world war with its increase of tuberculosis has given much food for thought. In order to prevent similar developments from the start and still further to improve combative measures, the ministerial council for the defense of the Reich has issued a decree regarding tuberculosis assistance by the Reich. The Reich health leader, Dr. Conti, discusses the contents and significance of the new measures in the *Politischer Beobachter*. To the old age pension scheme which provides for every insured German the decree adds tuberculosis assistance for every one who has contracted tuberculosis with services which will prove adequate and successful for preventing epidemics. It provides for treatment of the sick person up to the time when he regains his health or is able to resume his work without fear of infecting other people. It provides for continued supervision of his state of health and also cares for the family of the sick person whose economic distress has so often in the past induced the patient not to undergo the necessary sanatorium treatment. Fundamentally new is the provision that clinical treatment in a hospital for tuberculosis or a sanatorium is granted immediately for purposes of observation and reliable assessment of the chances of recovery. Social insurance and tuberculosis assistance by the Reich will thus in future be the main pillars supporting the fight against tuberculosis. There are at present thirteen hundred tuberculosis advice centers of the health offices in full operation. Over one million seven hundred thousand X-ray examinations have been made and two hundred forty thousand X-ray photographs have been taken in the centers. Over six million people have been examined since the outbreak of war by the X-ray section (*Sturmabteilung*) of the S. S. Thousands of previously unknown cases were thus diagnosed. A certain increase in cases of tuberculosis will be unavoidable even in this war. The decree, however, even at this stage creates the organization and financial foundations for a successful fight against tuberculosis. We have made certain that tuberculosis will not threaten national health during the war.

DVB of September 12 adds the following details. Under the new decree welfare societies and regional welfare associations will be created which will grant tuberculosis assistance to the rural and town population on the application of the health offices and in collaboration with them. On principle tuberculosis assistance is free of charge; it includes treatment, isolation and medical care as well as economic support for the patient and his family. The welfare associations grant tuberculosis assistance if the taxable annual income of the patient does not exceed 7,200 Reichsmarks and unless the necessary assistance is granted by a social insurance institute or in some other way. The limit is raised by 1,200 Reichsmarks for a married couple and by 600 Reichsmarks for every additional member of the family. Tuberculosis assistance may, however, also be granted if the taxable annual income of the patient exceeds this limit, if there is a danger of the necessary measures not being carried out without assistance. In such cases the welfare associations and the recipients of tuberculosis assistance may, in accordance with the civil code, demand a proportionate refund of the relative expenses from the persons responsible for the patient's upkeep. The decree is to become law after a transitional period fixed by the Reich ministry of the interior.

According to the *Deutsche medizinische Wochenschrift* (Leipzig) of July 10, in an article by Oberst Maier in the *Vierteiljahrschrift Schweizer Sanitäts-offiziere*, 1941, number 3, it is said that medical examiners have made too much allowance in cases of mental diseases when examining recruits for the army. Psychopaths, sexual perverts, hysterical people, schizophrenics

and maniacs, as well as persons with epilepsy and early recognized paralysis may all be accepted if they are put in appropriate posts and can be controlled and led by their superiors.

The *Deutsche medizinische Wochenschrift* (Leipzig) of July 10 contains a review of an article by professor Staub in the *Vierteiljahrschrift Schweizer Sanitäts-offiziere*, 1941, number 3, on the influence of drugs on mental and physical performance. He asserts that, in contrast to the first world war, the consumption of alcohol has been found not to promote the capacity for military operations but to be definitely detrimental. Amphetamine and pervitin (a synthetic amine chemically related to ephedrine) are indicated when a single special performance is wanted. There must, however, be a corresponding training and adequate nutrition. In the view of the writer these two drugs are a necessity for motorized troops, as they increase the performance and faculty of observation, while the monotony of driving and the loud noise tire the men and make them sleepy. It would be difficult to imagine a long distance night flight without these two drugs.

DR. MORRIS ON MEDICAL MISSION FROM AUSTRALIA

Dr. John N. Morris, a distinguished Australian physician, is now on a special mission to the United States in the interests of the Australian Central Medical Coordination Committee and the Australian Red Cross. His mission concerns medical supplies and equipment, the need of certain kinds of which is acute. Since the war began, Australia has increased the output of some medical supplies sufficiently to provide for the different military forces serving there and in other cases has found new sources of certain medicaments.

Surgical dressings, however, present a real difficulty, owing to the shortage of cotton. Australia also desperately needs quinine and other drugs used for the treatment of tropical diseases. Quinine cannot be used at present in Australia for prophylactic purposes nor for the treatment of any illness except actually established malaria. This situation is aggravated by the extreme shortage of suitable mosquito netting.

The Central Medical Coordination Committee has formed a Medical Equipment Control Committee which ascertains the stocks of drugs and medical equipment available, and the National Health and Medical Research Council of Australia has contributed to research work carried out mostly in the universities of Sydney and Melbourne toward the production of new local sources of drugs and biologic products. Dr. Morris points out that Australia has done a fine job solving many of these problems but that they need help. He has come to this country to give us the facts and to acquaint the medical profession of America with the situation in Australia. Dr. Morris is a member of the Australian National Health and Medical Research Council, chairman of the Victoria Red Cross, vice president of the Victory Society for Crippled Children, a major in the Australian Army Medical Corps Reserve, was the first president of the famous Australian Aerial Medical Services and was for many years chairman of the council and formerly president of the Victoria British Medical Association.

RUSSIAN WAR RELIEF

During the first year of operations of Russian War Relief Inc., the shipments to Russia and goods being purchased reached a total value of \$4,067,703.91. Edward C. Carter, president of Russian War Relief, announced on November 12 that supplies are being regularly sent to Russia in Soviet ships at no cost to Russian War Relief, which spends all its relief funds for American products and sends no money to Russia. The total of contributions to this effort to help wounded Russian soldiers and orphans and refugees in the Soviet Union is increasing each month and the supplies shipped are reaching their destination, 90.4 per cent of the supplies have been medical supplies, 6 per cent clothing, knit goods and blankets, 3.5 per cent foodstuffs and seeds, and one tenth of 1 per cent miscellaneous items. The head of the Russian Red Cross, Sergei Klesnikov, and Prof. Sergei Spassokukotsky, Soviet surgeon, recently cabled their gratitude to the American public and Russian War Relief.

ORGANIZATION SECTION

OFFICIAL NOTES

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

HELD AT AMERICAN MEDICAL ASSOCIATION BUILDING CHICAGO, NOV 20 21 1942
DR HARRISON H SHOULDERS, NASHVILLE, TENN, PRESIDING

(Concluded from page 1235)

Saturday Morning Session, November 21

MEDICAL SERVICE PLANS OF THE FARM SECURITY ADMINISTRATION

A. M. SIMONS
Chicago

The medical care plan is only a part of the general program of the Farm Security Administration which was started in 1935 with the announced purpose of helping low-income farmers to get a greater degree of independence and security. This general program is based on a system of federal loans accompanied by assistance in farm management and in the organization of local resources. Because the defaults in payment of such loans are alleged to have been due in large part to illness in the borrower's family, the Farm Security Administration introduced a program to provide medical service for its clients.

The first plans were started with little consultation with organized medicine and varied widely in many of their features. A few were legal corporations, some were farmer cooperatives dealing with medical societies and occasionally with salaried physicians. Sometimes loans were issued to individual families to pay for specific services with little group organization. Contracts were in some localities made with groups of physicians. This diversity involves no criticism. Given the existing state of knowledge or, better ignorance of the factors involved in the problem of organizing any general plan of providing medical service, it is necessary to proceed by trial and error with a certainty that there will be no lack of either trials or errors by those conducting the experiment.

These experiments did demonstrate that any successful plan of medical care must rest on constant consultation and close cooperation with the physicians who give that care and with the medical societies which alone represent the medical profession.

The Farm Security Administration has now adopted a policy of close cooperation with state and county medical societies and is pledged not to introduce any plan against the opposition of such medical societies. The 1940 report of the administrator of the Farm Security Administration says (Report of the Administrator of the FSA 1940 p 91)

The entire program has been worked out in close cooperation with the state medical associations and local medical societies. Before a medical plan is set up in any state a memorandum of understanding is drawn up by the Farm Security Administration representatives and the state medical association.

Any agreement for medical services must be satisfactory to the state and county medical society as well as to the Farm Security Administration and usually provides for termination if conditions unsatisfactory to either side develop. The present tendency seems to be to confide financial administration to a 'farm cooperative,' managed by the farmers but having no functions concerned with medical service.

The state and county medical societies to which this program has been presented have, with a number of exceptions, generally agreed that the income classes included in these plans were not previously receiving proper medical care and were at least partially dependent, and also that the physicians who had cared for them in the past received little for the services supplied.

On June 30 1942 there were 793 units of the medical plan operating in forty states covering 1017 counties and having a membership of 109,964 families including 578,894 persons. More than half of the persons served (316,925) are in the five states of Alabama, Arkansas, Georgia, Pennsylvania and Florida. The Agricultural Workers Health and Medical Association of California provided medical care for an additional 54,989 persons in 1941 and has expended about \$5,000,000 in provisions for transient laborers since March 1938, of which nearly \$4,000,000 was for medical care.

A request addressed to the secretaries of state medical societies in which Farm Security Administration medical plans exist brought much information of value in arriving at conclusions as to the professional point of view. In general the answers to the question as to the attitude of the profession brought a vote of nearly 4 to 1 on the satisfactory side. The states reporting lack of satisfaction were almost invariably those whose experience with such plans was confined largely to the earlier and more experimental stages. Criticisms were more frequently made in localities where economic conditions did not indicate a need for any special plan. Twenty one out of twenty eight states reported that the families included were receiving more or better or at least earlier medical care than they had received before introduction of the plan. There was almost equal unanimity of opinion that the physicians as a whole received more money under the Farm Security Administration plan than they had been able to collect from the same body of patients previously. It must be remembered that these plans were started in the depth of the depression when physicians in these localities were granting services to a large body of farmers who were at that time unable to pay much for it. Also that the loans granted to clients for medical services were very inadequate. The opinion is also expressed that better economic conditions have rendered such plans less necessary. In the first plans loans of as low as \$14 to \$20 per family annually were common and the total sum was distributed on a 'unit system' with basic fees sometimes amounting to only 50 or 60 per cent or even less of the prevailing fee schedule. Later plans increased this payment, but there are still many complaints of insufficient pay. Two excuses have been offered for such insufficient payment: (1) the appropriations fix a limit and (2) many of these farm families are semi-indigent and would be cared for by physicians with little or no pay. Neither of these explanations can be considered adequate but any financial differences are subjects for bargaining and adjustment.

There was in the beginning a lack of any clear definition of the medical care to be given and an absence of any competent and authoritative professional agency to decide disputes as to such limits. There have been some complaints of an excessive demand for medical services shortly after plans have been established especially for preexisting conditions while on the other hand some medical societies comment on the cooperation of the patients in restricting their demands to actual need. This would seem to call for advice to clients by the administration based on simple but ample explanation of just what services can be given.

A recent development holds far wider possibilities. The Farm Security Administration as an agency of the Department of Agriculture, in cooperation with the Interbureau Coordinating Committee on Postwar Programs is undertaking an experimental program to provide medical care to farm families without fixing any definite income limits. This program is being conducted through state and county agricultural planning com-

mittees, which are extensively organized throughout the United States. It is easily possible that this plan may expand to include a major part of the entire farm population.

The experimental character of this program and the necessity of close cooperation with the professional associations is repeatedly stressed in the material issued by the Interbureau Coordinating Committee. It is recognized that the extent of the medical care to be given must be somewhat limited but that "the first consideration" in any plan for medical care must always be the quality of the service and also that the high standards already set by certain prepayment medical care plans developed or sponsored by the medical profession can serve as guides in the development of local plans. The further policy is declared that "all strictly medical aspects of the program should be left to the professional groups concerned, while matters of business management will ordinarily be the responsibility of the farmers' organization."

State and county medical societies have done much to improve and perfect the Farm Security Administration plans. Extensive and costly surveys have helped to eliminate defects and insure better medical care. More accurate and intelligible limitations and descriptions of the medical services susceptible of being given for the funds available have been developed. This is the basic point of every prepayment plan. It is doubtful if any plan public or private, has ever given a fully "complete medical service." The problem is to determine just what is possible with the available resources and then to be sure that the public to be served understands fully just what can be given. Nearly all private and governmental prepayment schemes and especially those given most publicity are consciously or unconsciously guilty of deceiving those who are promised the service.

The medical care provided by these experimental plans while still limited at several points, is more comprehensive than in the previously existing Farm Security Administration plans, although it is recognized that "complete medical and dental care remains an ideal." The service now proposed includes general practitioner services as a base and, with numerous limitations, specialist, hospital dental, pharmaceutical and nursing services. In these plans monthly payments are adjusted to approximately 6 per cent of the income with a maximum of between \$50 and \$60 annually per family varying with the size of the family units. Since 6 per cent of the lower incomes manifestly will not produce the payments necessary to furnish the proposed medical service, a government subsidy is added which in some plans approaches \$100,000 annually.

Six of these experimental plans are in operation or in process of organization. Of the plans in operation, one each is located in Texas, Mississippi, Nebraska and Arkansas. Another in Texas and one in Georgia are about to start. The membership of these plans at present varies from 1,000 to 3,000 families. All are operated under agreements with organized medicine much the same as other Farm Security Administration projects.

The Farm Security Administration has expressed its desire to cooperate with prepayment plans operated by state and county medical societies wherever possible and at present is working in cooperation with such plans in California, Oregon and New Jersey and is negotiating with the Western New York plan.

The California Physicians' Service seems to have developed the most comprehensive plan of cooperation with the Farm Security Administration. Because this is based on a longer experience with more phases of the Farm Security Administration program than has existed in most states and therefore possibly forecasts a future stage of evolution, a somewhat fuller description and discussion may be helpful. The California Physicians' Service has established a Rural Service Department to care for all Farm Security Administration clients. The program is planned for statewide coverage of farm families, although it is at present largely confined to a few counties. There is an annual income limit of \$2,000.

Annual payments are graduated according to size of the family from \$20 for one adult to \$60 for a family of three or more. The patient pays \$150 for the first home call, care for adult chronic cases is limited, surgery for preexisting conditions is excluded, and x-ray and laboratory procedures require special authorization by the medical director of California Physicians' Service. Service is not given for alcoholism, refractions, workmen's compensation cases or conditions for which services are furnished by federal, state or other agencies. Ward service is given in a hospital for twenty-one days while the patient is under the care of a professional member of California Physicians' Service. The cost of hospitalization and

medical care in confinement is limited to \$25. The first \$5 for drugs which are also somewhat limited, is paid by the patient. No dental care is given.

Dr. A. E. Larsen, secretary and medical director of California Physicians' Service, says in a letter "The Farm Security Administration, the local Farmers' Health Association and individual patients have all expressed their complete satisfaction with the quality of the service." He also says "The physicians are receiving more payment from these families under this plan than was previously received from them." As to the attitude of the medical profession, he concludes "The decision to extend this contract throughout the state and to procure an active campaign of enrolment of additional families was made as a result of complete satisfaction on the part of the medical profession in the state as a whole. The action of the California Physicians' Service board of trustees in entering into this field was approved and commended by the house of delegates of the California Medical Association at their meeting in May of 1942, and further confirmation has been given the Council of the California Medical Association for the extension of this program."

There have been theoretical objections and charges that such plans are a step toward state medicine, "compulsory sickness insurance or socialized medicine." In evaluating such objections it may be well to consider alternatives. It has become axiomatic that this war will bring great changes in all institutions. News from Britain, Canada, Australia, New Zealand and South Africa reveals almost parallel movements throughout at least the English speaking world in the direction of greater intervention of government in medical care. The introduction of the Elliot bill in Congress, statements of President Roosevelt and the Social Security Board officials, the effort of some hospital insurance plans to invade the field of medical practice and many similar phenomena in a variety of fields are portents of a trend in the United States.

It is doubtful if head on opposition can greatly affect this trend. The House of Delegates of the American Medical Association has laid down the principles which determine its policy. The first of these is the foundation of all the others. It reads:

All features of medical service in any method of medical practice should be under the control of the medical profession. No complaints that this principle is infringed in any Farm Security Administration plan have been reported.

This would seem to be the most general and basic test of the acceptance by the medical profession of any plan of payment for medical service. All other phases may be subject to bargaining and compromise but any yielding of control of the standards of medical care to those unqualified to exercise that control is a betrayal of the trust which has been confided to the medical profession.

DISCUSSION

DR. GEORGE H. KRESS, San Francisco. The California Physicians' Service is a statewide project under the sponsorship of the California Medical Association. It operates as a separate entity, a separate corporation. Five thousand of our members are professional members of California Physicians' Service. It is now in its third year of operation. It started out with a large number of idealistic, all coverage provisions which almost ran it on the rocks. As time has gone on we have learned that you cannot give all coverage service at these nominal prepayment fees. The Agricultural Health Workers' Association which took care of the itinerant farmers who came into California has been put across on a very sound basis, as has been indicated by Mr. Simons. The experience we gained in that project has helped us greatly in connection with our Federal Housing Administration plans and also with the Farm Bureau work. Mr. Simons has indicated the restrictions that have been laid down. Even if these families have only \$2,000 annual income, it is mandatory that the first visit be paid with a price of \$1.50 for that first visit. There isn't any doubt but that it will go over in a very large way. The amount of money that has accrued to the physicians is far greater than they ever would have received from these families, because many of the recipients of this medical aid formerly were charity patients. This will undoubtedly run into thousands of dollars, the entire account being kept under a separate heading separate and distinct from all the other work of the California Physicians' Service. Do not go beyond the sound actuarial basic provisions that are necessary of observance if you want to put your plans across. We learned that to our sorrow in California. We have weathered that storm, and from now on we hope to go on to greater success. Through an extension of these other enterprises in connection with the Federal Housing Administration

and the Farm Bureau Administration, it is possible that California Physicians' Service will be able to put across a program that will be one of the outstanding expressions of medical service to lower income groups in the entire United States.

DR A T McCORMACK, Louisville, Ky. We are either going to take care of our farm population or we are going to destroy our civilization. The time has come when, having stabilized our urban centers and our industrial relations to a certain extent and made them independent, they have got to come back and help the farmer. This contribution is an enormous one, and there is a collateral obligation on our part. We not only must maintain the principles which we have established but must gradually realize that there is a difference between the demand for medical service and the need for medical service. Up to the present time, is a profession it has been our practice to respond only to demand for medical service. A man has a pain he has a fever, he has some symptom and he calls a doctor. The doctor sees that particular patient, who frequently is not the one in the household that needs the most medical attention and he doesn't see the other members of the family when he is there. The Farm Security Administration is making a notable contribution and I hope that as soon as they have finished with the great empires of Texas and California and New York they will get to the rural sections of the country where they are absolutely dependent on agriculture whose whole civilization is based on it, and who realize our obligation to the farmers of our country. We will welcome with open arms in Kentucky the Farm Security Administration when it comes and will promise it complete cooperation, and we will also promise it to do the very best bargaining we can for the benefit of the medical profession.

DR HOLMAN TAYLOR, Fort Worth, Texas. There is an element of danger in the new developments of the Farm Security Administration medical service concerning which I should like to ask the author. Under the earlier plans—at least down our way—and under an agreement that our council on medical economics made with the Farm Security Administration there was a measure of protection given the doctor in the matter of medical malpractice damage suits, and with us the doctors were given practical control of the service for which contract was being made, and of the money by which payment was to be made. Down our way the doctors are taking the matter over, and I think you will be told that we are running the medical end of it just as was intended in the beginning that we should do. However there is now the element of medical malpractice which must be considered.

MR A M SIMONS, Chicago. That is just one of the points that I would say required a good attorney, which I am not to go into, but it is one of the questions that you can work for. You can say "If this situation regarding malpractice does not protect us, we will not go into it." The ace in the hole that the medical profession holds in every single one of these debates is that nobody has ever found the way yet to give medical service without physicians. That doesn't mean a strike. It simply says that you say "We can't give the sort of medical service we ought to unless we have these protections and we won't deceive the people." There are certainly dangers in this. There are always dangers in social experiments. We made a lot of mistakes in the prepayment plans, but I think we are coming out ahead. The Farm Security Administration made an unmerciful lot of them in the beginning. Don't say South Dakota to one of them or he will throw something at you for what they did up there, but they are beginning to realize the fact that they need the physicians, and they need the organized physicians—the medical society. Now the question is Are we ready and able to give the information and the help they want? That may not be very satisfactory, Dr Taylor but I think the fact is you have to work out all these details always with the one thing in mind that you are not going to let them have control of giving the medical care. There, mind you is the danger, because you have in your Social Security in a lot of the social services and in most of your industrial affairs a large part of the medical care.

DR TAYLOR. In one of the counties that is now trying out this new idea the contract was made by a cooperative group of farmers organized along the financial lines recommended in part with the county medical society itself. That particular society does not happen to be incorporated. If it was incorporated under the laws of our state, it would be a different proposition. But what is the aspect of a cooperative agreement involving a contract with the county medical society and not the individual doctor?

MR SIMONS. I couldn't answer those questions but I would say you had better get some good legal opinion on it and find out if you ought to incorporate it.

DR TAYLOR. The doctors who are going to render this service must be protected against the malpractice laws in our state. We recognized the seriousness of this situation some time ago and undertook to get our legislature to warrant the formation of simple partnerships in counties for the purpose of serving groups of lower income workmen. We didn't get it because of the intervention of the osteopaths. They wanted us to make an insurance problem out of it, and it is not an insurance problem, it is a partnership. A simple partnership for the purpose of taking money however we can get it honestly and honorably and dividing it among ourselves for an honest and honorable service. We failed to get that enabling act through the legislature. It we had that, we could solve that problem of service to the farmer, to the industrialist and to whosoever may be concerned and we would then be absolved from the damage suits that can come through partnerships.

DR JOHN HAROLD FITZGIBBON, Portland, Ore. It has been our impression on the West Coast that a great many of these people from the distressed areas have moved out into war industries. I wonder if any one connected with the Farm Security Administration picture could give us an idea of how many of these people have drifted west and elsewhere into war industries. There must be a tremendous absorption of them and I should think that would profoundly alter the economic situation in the areas from which they come.

MR SIMONS. I can say that Dr Mott and others told me they had studied it somewhat, and they recognize thoroughly as I mentioned twice in this paper that changing economic conditions are changing the need. That is a thing we always want to keep in mind. In the ten years I have been with the American Medical Association the changing economic conditions and the changing source of conditions have changed the picture over and over again. I don't think there is the need for Farm Security Administration help in many of the states that there was.

DR WILFRID HAUGHEY, Battle Creek, Mich. I would like to interject one thought. How many farmers are there left in Kentucky and Tennessee? We have had them come into Michigan by the thousands and tens of thousands. One company alone in Michigan is importing 20,000 a month.

DR McCORMACK. That is one of the greatest difficulties we have. Whenever there is a boom in Michigan they come down and induce our innocent people to go up there. They pay them high wages and charge them high prices for living and they get bad habits. Then just as soon as the bust comes they hire buses and send them back to Kentucky broke with the same extravagant habits Michiganders have. Our problem is very much enhanced by having that association.

INTRODUCTION OF GENERAL DAVID GRANT

COLONEL FRED W. RANKIN. One of the outstanding features of the present armed services is the rapid expansion and high efficiency of the Air Corps. It started as a relatively small part of the Army, and today it is certainly one of the dominant forces if not the dominant arm in the whole service. With that expansion the medical forces of the Air Service kept pace and today I think there is no more outstanding achievement in the Medical Department than the noteworthy efficiency and *esprit de corps* with which medical matters are handled in the air. That this is the fruit of the labors of one man largely who had the good judgment to surround himself with some very efficient and energetic and alert young officers. I believe there will be small disagreement. That man is General David N. B. Grant, the air surgeon, whom I have the pleasure now to present to you.

MEDICAL PROBLEMS OF THE AIR CORPS

BRIGADIER GENERAL DAVID N. B. GRANT
AIR SURGEON, UNITED STATES ARMY

We have built our service along the plan of first getting *esprit de corps* among our officers and integrating them into the air forces. We have also built our service along the plan of endeavoring to put men into positions in which they are fitted. We have made a hobby of it.

We know we make mistakes, but I was very much gratified that the officers from Jefferson Barracks the other day told me that out of seventy-one officers stationed at Jefferson Barracks less than 1 per cent were not assigned to their specialty. There are a great many jobs in the Army that have to be done, but we are certainly trying to take the outstanding men putting them in as heads of our services, and stabilizing

those services so they can't be moved, and assuring the men that they are doing the work for which they have been fitted.

We have gone beyond that. I myself feel very strongly, and have for years, as I see this picture unfolding that the army medical services have a very definite goal to better these doctors for their civil work when they get out. Medicine has become very much specialized, as you know. Aviation medicine covers all the specialties. We feel that with the training we are giving our doctors, whether surgeons, cardiologists or what not, they have a broader picture of medicine when they get out. We also think, this being a global war, that we have got to think in terms of global medicine for the future. The question of tropical diseases in years past has been written into textbooks, as far as I myself know until this time, just to make them a little bit thicker. We have got to know something about that, all the doctors have got to know something about that. We have men today in South America Africa and, three days later in Nome.

We also feel that we have an obligation to the public to turn these boys back in better shape than that in which they came to us. We are doing a tremendous amount of salvage work today. Not only are we doing the salvage from the standpoint of operative work, but I am speaking of the morale and the mental side of it. For instance, yesterday orders went out to all our hospitals that there would be started immediately what we call inpatient occupational therapy. All our patients will get some form of instruction, whether it is radio mathematics or what have you while in the hospital. The patient will get bed exercises. He may be able to do only finger exercises the first day but he will graduate up until he gets out of bed. We feel that by doing that we shall return these soldiers to their companies on a duty status, with a little ambition to pick up and go ahead where they were just standing still before.

We have arranged a form of certification which we send to the company commanders, our estimate of that individual whether he is interested in radio or what have you. We give them lectures on current events in the wards moving pictures of something along the military line which is going to help them. The preliminary estimates in the one hospital where we have tried it show that that has knocked down our sick report—I mean people just coming on sick report—around 25 per cent and we know we are turning back to the companies better men not only physically, but mentally.

This is a tremendous war. We cannot afford to lose manpower in any respect. We have taken men with an arm off. The commandant at Kelly Field today is doing one of the best jobs in that line that the air force has had. He has his arm off at the shoulder which he lost about six weeks ago. In other words we want to salvage those people and give them an interesting life, and let them know they can carry on. So far, we have been fairly successful.

With reference to the medical societies all of my hospitals have been instructed to contact the local societies and if possible, affiliate with them. I hope they are doing it. I think there should be the closest cooperation between military medicine as practiced in the neighborhood and civilian medicine. With the shortage of doctors I think we have got to help one another and I can assure you from the standpoint of the army air force that help will be forthcoming whenever it is needed or asked for.

MEDICAL SERVICE PLANS

JAMES C. MCCANN, MD
President of the Massachusetts Medical Service
Worcester, Mass.

It is probable that if this world change does influence the practice of medicine and it is difficult for me to think of the millions of boys who are going abroad—many of us may join them within a short time—who are going to contact this undeniable rise of the common man in the rest of the world who are going to get in personal contact with social institutions and experiments all over this world which are being improvised to meet the demands for security and of economic security and social protection of the common man, it is doubtful if they are going to return and not ask us what we have done so far as fortifying the position of the common man who needs medical care in America. I doubt that he will be satisfied if we say to him, "We have given your mother, your father, your brother and your sister adequate medical care as charity." I think that is the crux of the problem.

Of the experiments that have been devised, the prepayment plans of medical care have been looked on as probably the most effective approach, under the auspices of the physician, to

solving the problem of the care of the low income group. I am just going to discuss in outline what has been done in building Massachusetts Medical Service. I certainly do not offer it as a sample or plan especially for it, but I offer it as a tree on the branches of which may hang the basic problems with which any group is confronted that endeavors to establish a prepaid medical system for medical care. The answers to these problems I can tell you, having been one of the active members in organizing the Massachusetts plan, are not very easily available, in fact, they are most difficult to get.

The first basic problem is: When are the physicians in a state ready to support a prepayment plan of medical care and how are you going to acquire the support of the profession within the boundaries of the state, because without a list of participating physicians you have no cooperation?

There are various factors which have brought the men to a position of willingness to support a program of premedical care sponsored by a medical society. Going across the country, we know this action was precipitated in Michigan and in California by a very decided threat of passage of a law for compulsory health insurance.

Massachusetts sampled another type of pressure although it wasn't serious, and it is similar to that which has appeared in Oklahoma City and in Washington D. C., and that is the appearance of the consumer cooperative. The other motive—it was preexisting in Massachusetts before the appearance of the consumer cooperative movement—was a determination on the part of the profession to accept the fact that there was a problem in the distribution of the cost of decent medical care and that they were accepting it as a responsibility and were going to try to find a solution for it.

In the achievement of support of the profession, I just briefly outlined how we accomplished what we have accomplished to date in Massachusetts. I think it is a fairly satisfactory start because of the effect on practicing physicians. I think within six weeks we have achieved an enrollment of well over 20 per cent.

The approach was this. We had a special committee which was empowered to work out the program for starting the corporation. They had to report through the various committees the council and our legislative body. The proceedings of the council were published in the *Journal*. That was read I think—I doubt how widely—by the practicing members of the state because some are interested in proceedings, and many are not.

In the realization of that weakness and that approach, last year all the district societies were approached and spoken to along three lines: first the need of such a plan from the point of the threat which faced us, second a specific discussion of the type of corporation that was going to be created from the point of view of the interest of the physician as to whether or not he was going to lose control over the practice of medical care as far as basic medical problems are concerned and third the financial problems which always interest the physician and are involved in the two fundamental questions of cost to the public and the fee schedule for compensation to the physician.

This was followed up when all data were approved by the commissioner of insurance, by the circularization of every physician in the state with a brochure. Through the summer we got out these separate supplements apart from the *Journal* for fear any such information would be lost in the depths of the *Journal*. When everything was ready we circularized the physicians with a brochure with information containing the basic philosophy in back of it, all data, by-laws, subscribers' contract and the rules and regulations so that before we asked a single physician to participate in the corporation he at least had available every bit of information which as an intelligent man he was entitled to have before we asked him to sign a contract.

Simply mailing the data brought us 1,400 men. We followed it up in a few weeks with a postcard, knowing that the doctor's weakness is to place all mail under the pile of issues of the *Journal*, and we acquired another thousand signatures. We followed that a week later with a pressure letter, and we have over 50 per cent of the active men in the state at present. We are going to follow that with active solicitation within the next few weeks by the lay members of the Blue Cross, helped by committees of physicians who are appointed in every district in the state and it is our hope that before we effectively start the sale of this contract we shall have enrolled 60 to 75 per cent of the physicians within the period of two months. That, of course remains to be seen.

Next comes the basic problem of how you are going to establish this type of corporation. There have been many approaches in all the states through the country. One state will set up these corporations in small areas, even in cities; other states have set them up on a statewide basis, as have California, Michigan and Massachusetts. Others require that before a statewide corporation can sell in a district it has to have the approval of the local group. Massachusetts has not accepted that as a safe approach from the point of view of securing sales of an adequate number of contracts. This matter was threshed out recently in Michigan, after a year and a half of functioning, and the house of delegates there voted 'No' on censorship—which it amounts to—by the districts as to whether after the state society has started the venture, it should be sold in their sections.

Another problem that must be looked at very carefully is whether or not this type of corporation is going to function in a rural area in industrial state or a state that has a balanced economy as far as industry and agriculture are concerned.

We have an urban problem of 94 per cent and a rural farm problem of 16 per cent. On the basis of wage earners which this primarily involves, we have 35 per cent of the industrial manufacturers, our retail group 19 per cent and all industrial activities represent but a small percentage. So immediately our problem broke down on the fact that we had primarily an industrial problem and, secondly, a retail sales problem. Breaking it down into geographic areas we found that our wage earnings were only 36 per cent in metropolitan Boston in the industrial group and 64 per cent in extrametropolitan Massachusetts. In other words the whole state looms very large in this problem, as compared with the important metropolitan area.

As to the type of organization since enrollment is related to the number of people whom you can procure in a single group we found that 75 per cent of our wage earners were in industries employing from 100 to 1000 and over. We don't get much over for an organization like General Electric which now is employing 18000 or 19000 people whereas in Michigan General Motors delivered a subscription list to their cause of 160,000. Again these larger organizations are distributed between 75 and 80 per cent in extrametropolitan Boston.

You make very important commitments when you undertake a project like this, and I think one of the most important ones is that we go before the state legislature and ask for an enabling act. I think I can very quickly give you the import of what it means to have a law put on the books when I quote this from the recent address of the president of the Pennsylvania State Medical Society:

Even now threats can be heard of legislative action to modify our own enabling act to place its control under the state. This must be anticipated by early action on our part.

So we cannot be afraid of proceeding on the basis of legislation. I don't think doctors would undertake the risk or assume the risk of forming such an organization nor do I think you could have the cooperation of the stable type of citizens in putting across such an organization as this unless we had the basic protection afforded by the law of the state.

There are other important commitments to which you are going to give your hand in the simple process of getting an enabling act. First, you are going to determine the eligibility of physicians to participate in the program and that is directly related to the problem of standards of medical care. That may not be a large problem in some states. It was a very difficult problem in the state of Massachusetts. The osteopaths in our state are licensed as physicians under the same law that we are licensed. There are only 270 of them but in the state of Maine, where they have their own licensing law they are flooding the state. Our enabling act is so worded that they will continue to participate. I don't believe we could have had a law from the legislature unless any licensed physician could participate.

We are also faced with the problem of substandard schools in Massachusetts. We have had two of them. It is a problem that other states do not face at all but I heard Elliott Joslin whom you all know, the authority on diabetes stand on the platform and make the statement that if it were not for the graduates of the substandard schools the other schools could not supply the numbers of physicians needed in the state of Massachusetts, and there would certainly be inadequate medical care if we went short on the number of physicians. For years the profession has fought to have that situation corrected, but it is filled with many implications that can't be brushed aside by the statement that we won't qualify the men who are

graduates of substandard schools. Also when the Army is not taking the substandard school but is taking the standard school graduates, the proportion of substandard school men has risen on a percentage basis in the state of Massachusetts.

Another problem you introduce when you ask for an enabling act is the question of supervision of your corporation, and that is serious. Is it going to be under public welfare? Is it going to be under public health? Is it going to be under insurance? Most state societies have chosen insurance because, I think, knowing physicians, we would hesitate to see in our name the accumulation of the vast public funds which will be accumulated unless it is watched by an organization like the State Department of Insurance. There is no question that its point of view is that of insurance and not of medicine, but the practical facts remain.

We have faced this problem of the insurance point of view being interjected. I think so far we have come along fairly satisfactorily. When you put it under the Department of Insurance and work through a state bureaucracy you make another interesting observation. You can work for months and establish basic plans and premises and then find that in two minutes when it is put on the desk of the Commissioner of Insurance he doesn't accept the word and advice of a subordinate and it is thrown out the window.

We had to sit and argue to keep the osteopaths from writing a clause into our own by-laws. We had to have a formal hearing before the Department of Insurance. We put up \$25,000 to start the thing. Under the ruling of the department at present we have \$5000 to start with. The rest is frozen. After we had our whole organization completed and ready to sell the public and the by-laws approved in May we received a letter in September that they wanted to change the by laws. I think we are going to stand our ground without any question.

Another important problem with regard to the enabling act is that you are going to determine very definite matters with regard to control of your corporation so far as the medical profession maintaining its proper guidance on distinctly medical matters is concerned.

We have felt that to have an effective board it should not be too large. One of the men very honestly told me he thought at times that the meeting of his board looked like a medical convention. I think that will have influence on the support which the corporation is given by the public. We have this setup: one third of physicians and this one third subscriber representation was a requirement of the enabling act. That is why this comes in. Then we have one third open using here eminent laymen who can really give your corporation standing before the public and give the type of advice which is necessary in such a large effort if it succeeds.

How about the vital medical man? We have pulled out the one third physicians as a central professional service committee functioning within the board of directors. This seems to cover the things we are concerned about and this group has the power having advisory help from district committees to initiate all actions on these matters into the board of directors.

I will say that working with these groups of laymen, and bringing our program to completion as far as readiness to sell to the public is concerned there has been no difficulty with reference to these matters which concern the profession. That assures a carefully studied and professional point of view as the basis for action on these matters and so far we have been very successful and effective.

One question has been discussed very widely over the nation, and of course, being an industrial state it is a very important problem with us and that is the representation of labor on the board of directors. Although organized labor may represent about 10 per cent of the working group of the population, nevertheless I heard an important member in a manufacturing organization state the fact that their organization did give them the power because they accept the self discipline. Some of the states started without representation of labor and they have told us they regretted it and are now moving into a position of representing labor.

I talked with the major manufacturing men who were our representatives and they were in agreement with the view that ultimately labor is going to have representation in all these organizations and it is much better to pick the type of man you want in your organization in the beginning, rather than to have him hand picked for you later and not have as satisfactory an individual.

There are other problems. There is the question of income limitations if we offer service contracts to the people. It is hard to see how a physician would become too enthusiastic

over working very hard to establish a pure corporation. I think people are looking for a setup where they will pay a premium and get a service, and Massachusetts Medical Service is based on the fact that fundamentally our medical service contract is the one we are interested in.

All over the country there has been a wide diversity of approach to this problem of group income limitation. It is an unsatisfactory problem at best. California has a level of \$3,000 for eligibility. Buffalo has a level of \$3,000. Utica has no level at all. New Jersey started with a level of \$1,600 and found they had to raise it for practical requirements. You just couldn't enroll an adequate number of workmen to start such a corporation if that was the level. Michigan State established \$2,500 for the family and \$2,000 for the individual. Those same figures were set by the state of Massachusetts. The labor representative when we had our first meeting made the request that he thought it would be more equitable if the large family group was eligible up to the level of \$3,000, because in effect, the laboring group looks on \$3,000 as the upper demarking line for the wage earner. Beyond that you get your foremen and men who have better positions in industry.

We found that in our manufacturing group the average income was \$30 a week, in the retail group \$22 a week. This was in 1941, before we had time and one half, and war industries came into the picture.

We found that the \$2,000 limit for the individual took 83 per cent of the wage earners, and \$2,500 for the family took 91 per cent of the wage earners of the state. To approach such a program with much lower levels would not really meet the problem. That is how we felt in Massachusetts. There is the question of whether, with the large family groups, it should be higher or not. It is an eminently unsatisfactory approach.

The employer in many instances has told us 'We won't reveal the workman's income.' They are going to now. Many of them have to reveal it through the income tax, and we considered whether or not the report through the income tax should be the level as a means for determining the income groups, and we were told flatly by the Department of Insurance that they wouldn't accept it. That is all there is to it. What the department tells you usually is the basis on which you function. The patient will state his level of income. We have to accept that at the time of enrollment and if it changes the only method of determining that is when the patient comes in with his card when the physician can ask 'Are you still below or above this income situation?' That is an unsatisfactory situation, but there is none better until somebody finds it for us.

The next big question which disturbs many groups is: Are we going in the insurance business? In other words, in addition to the service contract shall we have an indemnity type of contract above the level set for the service group? There are two reasons why I think we are forced to do it. The fluctuation of income in the state of Massachusetts through the years is now getting up into astronomical proportions. But if you take your median and put your large group enrolled right through here, what are you going to do to them in a year? They are back on the service, they are above it, they are back again. Are you going to enroll them next year and tell them 'You are out' and then ask them to come in? This indemnity contract seems to be a buffer contract when they stay in the coverage but when they need service again it is available to them automatically.

The other point of view in the sale of these contracts is that you can't interest the group in industry unless you have something to interest the foreman, interest the man in charge of the group below because the warmth you receive is in direct proportion to whether or not there is something in this proposition that interests the man at the top.

Now comes the major problem of the initial contract. What is going to be your type of approach? Massachusetts definitely accepted the approach that we would base our experience on the practical experience of the other states. As Mr. Simon said, they started out with the idea that they were going to give complete medical service right down the line. We learned from the groups that it couldn't be done, so we haven't attempted it. As a matter of fact, we were warned that the reasonable approach to this thing—they gave us figures—was through partial coverage and then endeavoring to develop it to complete coverage.

Massachusetts took the experience from all over this country, and I might say that the whole picture has changed with those who adopted complete medical coverage.

Michigan is selling a partial coverage contract. Buffalo or Utica, I am not sure which, is canceling complete medical coverage and selling partial coverage and, I believe, changing

the indemnity basis. So we started in and said 'We will take the type of coverage which is actuarially sound.' I think you have got to do three things to start this thing. You have got a sort of tripod. You have your ideal, you have sound actuarial practice and you have what the public will accept and buy. Those bring you at present pretty much to a surgical and obstetric contract. When both types were offered in Michigan, 160,000 partial contracts of the surgical and obstetric type were sold as against 5,000 for complete medical care. That is some what related to the difference in premium costs. In our picture, starting with this surgical and obstetric coverage, it covers 62 per cent of the hospital care. When we are established on a sound basis we intend to extend it to a complete hospital coverage picture, which is the one which New Jersey is starting with at present, plus such coverage in the home and office as seems, from the experience of other groups and studies of our own, to be advisable.

That brings us now to the basic problem of finances. One problem relating to that is the question of correlation of this endeavor with the Associated Hospital Group, and that is a problem which is under development and, you might say, a matter which is under controversy in different sections of the country. That controversy is related to whether or not the Associated Hospital Group of the Blue Cross System and the Medical Plan Groups shall be intimately related or whether they shall be quite divorced. It is a very important problem.

One of the bases of criticism for compulsory health insurance is the cost of maintenance of the corporation by virtue of payments to lay members and the statement about the large number of lay members involved in the German system of compulsory health insurance is one we know of and is quoted repeatedly. Are we going to place ourselves in the same position, of duplicating too much of cost in the way of duplicating personnel, duplicating office setup in the distribution of our program? There are those who seem to identify the Associated Hospital insurance program with the Medical groups, in the fear that medicine may be taken over by the Hospital groups. In our section at least, that is so. To me, I can only visualize the Associated or Blue Cross Systems as a financial intermediary between people and the financial intermediaries the same way that our corporation is going to be the financial intermediary between the people and the individual physician.

I just quote to show you how this problem is developing. It is a public statement, so I presume it is proper to quote a recent motion voted in Michigan. That Michigan Medical Service be separated from Michigan Hospital Service at the earliest possible moment consistent with sound actuarial practice. It is a very difficult problem. Massachusetts is starting out with a very close and intimate tie between the two organizations. We have had the best of relationships there. I hope it will work out. Nobody can say it is right, nobody can say it is wrong. It is one of the questions that time has to show us the way. It seems to me that we are mutual allies. We are voting for the basic problem of preserving a voluntary approach to the problem of settling the costs of medical care on an insurance base and I understand that in the recent hospital group it was the Blue Cross members who fought most forcibly to bring the hospital group to a definite stand on many problems relating to relationship with the government. I think we are protected by their position. If the voluntary scheme disappears, they go. If the voluntary scheme disappears, we shall probably be serving some other way whether under the government or what not. So I think, maybe at the expense of giving the patients the greatest benefit for the premiums paid, if we separate too far from the group we may be jeopardizing our chances for success. That, of course, is entirely debatable but it is the point of view on which we are proceeding.

The other important problem relating to finances is the question of the premium rate. Buffalo started with complete medical care, and considered the surgical, Utica, complete medical, and covering hospital and surgery. New Jersey started with complete medical care, and I think they are starting only with hospital and surgery. California, with a comprehensive plan, is restricting sales and is selling surgery. Michigan has canceled the comprehensive plan and is going to surgical.

I want to call your attention to the various premium structures: benefits allowed, fee schedule, the expenses, and the service that is created. That each of us should be stumbling along with no correlated body of knowledge with regard to these many difficult problems with which we are confronted, I think, is unfortunate. I just give you this to look at. The Blue Cross books are correlating in loose leaf form the accumulating data of all their various plans. Yet Michigan, Massachusetts and California have a wealth of experience on a

definite social experiment in medical economics, but the knowledge isn't correlated so we can use it in the states. These many problems I have just outlined I thought you should know. Those of you who have been through it are well aware of them, but these basic problems we haven't yet organized so that we can get information on them. There is certainly no one answer to all of these problems but the many difficulties the different states have gone through in tackling them, from the embarking act up to determination of premiums. I think might well be correlated, analyzed and put into printed form so that with the changing problem—you have seen how it has changed even in the states of California and Michigan, which have been in it for some time—we can strengthen each other by the experience of other states and not jeopardize this whole approach to the problem of prepaid medical care by repeating the mistakes of others and by wondering "Where can we get help on this specific problem?"

DISCUSSION

DR WILFRED HAUCHMAN, Battle Creek, Mich. I know something about this Michigan plan. I have been on the committee that has been working for about four or five years developing it. I am vice president of the plan, because I refused to be president. I do not live in Detroit where the office is. I live in Battle Creek, and it is a three hour trip to Detroit and three hours back again. In working this thing out, we had forty four meetings in Detroit in one year, where we started in about 2 or 3 o'clock in the afternoon and finished about 2 or 3 o'clock in the morning. We had no data to go on. We had nothing to start with except our bare hands and what we had inside our noddles on insurance, which wasn't too much. It was a question of cut and try, as you have just been told.

This thing has been worked out in Michigan over a period of many years. Our Economics Committee made a very detailed survey of the state over a period of four or five years ended about 1930 or 1931 and brought in a report to the state society with a proposed plan. That was finally considered by the society in 1934 and rejected. Then our committee went to work again and we finally have a plan. We have had all the stumbling blocks you have just been told about and some they haven't told you. We are still altruistic. We are still paying for all the surgery done in the hospital, and we are considering right now paying for some surgery in the office because our hospitals are so full we can't get patients in. We haven't actually done it, but it has been authorized as soon as our administration thinks it can be done. You have been told that we have been ordered to divorce from Michigan Hospital Service. That is true. Our house of delegates voted to separate as soon as it is actuarially sound. I don't know when that is going to be but what we are now considering is a third corporation to do the sales and to do the contract with industry to make the collections and so on and then turn the money and the contracts over to Michigan Hospital Service and to Michigan Medical Service to work on.

We have over 455,000 people being taken care of. We had a revolt, as you were told. We had one county society that flatly refused to cooperate ever since we started and they spread the gospel to about three others. There were three more counties on the fringe of joining that group, but at the last meeting of the state medical society in September we ironed out some of that—not all of it. We still have the unalterable opposition of certain groups. They will not fill out our blanks. They send their bills to the patient. The patient has to forward the bills to Michigan Medical Service and up to about two or three weeks ago, they refused to accept our checks in payment. We had to send delegates to one of those counties to go with the patient to the doctor's office and pay in cash and accept receipts. We did that for a long time. We sent \$15,000 or \$20,000 up to the bank in that town under the Fidelity Insurance. The man couldn't carry more than \$500 at one time so he would have to go to the bank and get \$500, pay that out, and go back and get some more. They sometimes had \$15,000 and \$18,000 to pay out during the trip up there, so you can see the nuisance it was. That county has finally voted to accept our checks, so we think we have that solved. They are not cooperating but approximately 80 per cent of our doctors are cooperating.

We have changed the method of cooperation so that the doctor doesn't make any rash promises, and we are not holding him very closely to it. If he will participate and will render service and make reports, that is all we want. We are not too strict about that, that is, I mean his signing that cooperation list. We are paying a good big proportion of our funds out to noncooperating doctors in the idea that these people are

covered by our plan and are entitled to the service and we should pay for it. If they go to a doctor who isn't cooperating, we pay for the service just the same. Two or three times, and once under the direct demand of the Insurance Department, we voted to not pay any more noncooperating doctors. We were getting along in pretty good shape at that time. We were beginning to see where we were getting pretty nearly up to black figures. Promptly we went back into the red, because everybody hustled in to get the work done before the date that they couldn't be paid for everybody whether he cooperated or not. We have been through that two or three times. We put that off for sixty days and then went through it again. We have finally decided that we will not make any such statement any more, we are going to pay for the services. But we are up against another proposition. We asked for reports for these services within thirty days and we are still getting some of them after two years. How can you make any actuarial plans when the doctor doesn't send in his bills for a year or two years? We have been told by the insurance commission that after a reasonable length of time we shouldn't pay those doctors. Where are you going to draw that line?

We started out with a rate that we charged for the services, and we have had to increase that rate. Last Wednesday night we voted another increase in that rate, which our actuarial advisers tell us will carry the load and ultimately get us out of the red. We are in the red, we admit it, everybody knows it. For about four or five months we prorated what we paid the doctors. We paid them 80 per cent of our allowances. We stopped that proration. We are going into the red. We are paying the bills as they come every month and yet actuarially and figuring reserves for bills that haven't come in yet, notices we have had from doctors that they have such and such a patient it shows us in the red. We don't know whether we are carrying enough reserve for that or too much reserve for that. But our experience is that about 40 per cent of the notices we get that there is service being rendered to such and such a patient don't actually pan out into a liability that we have to pay. Maybe that patient didn't go to the hospital at all. Maybe there were a lot of things. Maybe the doctor simply made up his mind that he didn't need that money. We don't know why, but we do know we are notified of thousands of cases in the office that we never have to pay anything for, and those notices come in thirty days, sixty days, ninety days or a year late. We have set up a sort of plan, from our experience for two years and over, that we think estimates what the bills are going to be. We know which months of the year are the heavy ones and which months of the year are the light ones.

We think we have rendered a good service. We are paying our doctors fees that are commensurate with the fees they are getting in private practice. There are some items on which we may be low, and there are some items which we know are high but we are trying to pay liberal fees for the service, and we are paying the same fees throughout the state in industrial centers or in rural centers. We are doing that with the deliberate idea that some of the doctors in some of those districts weren't getting enough money anyway.

I didn't tell you all about the start. There were two counties in our state that worked out a plan and wanted to put it into effect and were going to do it when our state committee finally decided to go at it again. That information was all consolidated and worked out, and we actually started our work in Detroit.

Some of us wanted to put a restriction on elective surgery, not allowing elective surgery on pre-existing conditions until the individual had been covered with his protection for a reasonable period of time. We didn't do it. We know now that was a mistake. We should have done it. Forty per cent of the money we have paid out to doctors has been for tonsillectomies and appendectomies, and we have paid out—I don't know the exact figure but it is nearly three million dollars to our doctors since we have been operating. We are paying them about a quarter of a million dollars a month right now. That is big business.

We are way in the red. Some of you may know how much we are in the red. I am not going to tell you. I don't know. We had our whole affair audited by a group of nationally known auditors which has just been finished. They couldn't audit beyond the first of July of this year, and in getting those figures they had to make tremendous numbers of estimates. They told us how much we were in the red then. The figures that were given us last Wednesday night showed, for the first time in several months, there was a balance in the black for the operation of that month. So we think we are beginning, to see where we can work it out. A plan was given us with some

little increases in premiums that we charge and a considerable change in our operation where we can pay off and get out of the red we hope. The same actuaries told us eight or nine months ago that from the trend then we would be out of the red very soon, that we were getting out of the red at the rate of \$20,000 a month at that time. Well we were, but we weren't because, under orders from the insurance department we told the nonparticipating doctors we weren't going to pay them any more and promptly we went back in the red, way back in the red.

This is a problem that takes a tremendous amount of study as you have just been told. We were wishing all the time we were going through this thing there was some bureau that had some information. There just wasn't any. This was a new thing entirely. We have information now we have got plenty of it. California has plenty of it. I think we have more than they have. We are perfectly willing and anxious to sit in with any other states that are working on this thing and try to let them avoid the mistakes we made. We made mistakes yes we made plenty of mistakes. We did it honestly. We did it trying to do something for our people and trying to do something for our doctors. I think we are still making mistakes. I think we are covering too much ground in surgery. I still believe we shouldn't do all this elective surgery as soon as a family gets covered. We had one family that within a month of taking out their policy had seven tonsillectomies and three appendectomies and a hernia.

ALPHONSE M. SCHWITALLA, S.J., St. Louis. From the very beginning I have been critical of the whole Michigan Plan and with a good deal of wisdom some of the people from Michigan asked me to come up and speak on the Michigan Plan at the first anniversary. I was very glad I could do so because I acknowledged that I had been converted. But this last statement we just heard about being in the red perhaps might unconvert me if this thing keeps on going not that I think we should lose heart over the fact that there is a lot of red on some people's books but after all this is an extremely difficult problem to solve. I don't have to tell you that. The very fact that these gentlemen who are running these plans are still clamoring for the experience of others something to ease their own experience on is an indication of how difficult this problem is going to be to work out. In principle I suppose it is possible to work out a scheme that is going to put medical economics on a sound basis and is going to harmonize the fundamental practice of medicine the personal relationship between patient and physician and the responsibility of the individual for his own medical care and place that on a sound basis. Yet I am sure we have not as yet given enough thought in the nation as a whole to what we are about. That is the theoretical side. The practical side is an entirely different question. You know the menace that besets medicine today. There is no doubt about the governmental threat. You all know that the Social Security Administration has already in the back of its head forms for hospitalization care medical care and compulsory health insurance that are going to apply to both sides of this question the medical side and the hospital side.

I have a lot of feeling about this matter just now and as I said, a week would not be too long to discuss this but I think I would like to see the House of Delegates of the American Medical Association begin an evaluation of what has already been done and I mean evaluation not only in the way in which they have done so already by careful watching and careful study, but by some form of public pronouncement. I am not wise enough to say what they should say. I don't think any one of us is but I think the combined wisdom of the Trustees and the House of Delegates just at this moment that will give some direction to the state societies would be an extremely valuable thing. I myself feel there is tremendous danger in state plans and I say that on the basis of the experience of the hospitalization plans the Blue Cross plans. I believe these plans should start locally and as actuarial experience grows and as the homogeneity of a given area is going to be disturbed by the introduction of more foreign factors further afield as modifications can be made in response to that experience the plan can very well expand into a state plan. I say that because of the experience of the Blue Cross plans. Those have been most successful which have started locally and have expanded as actuarial experience could enable them to expand. In Dr. McCann's statements a few moments ago, about the big volume that the Blue Cross plans have gotten out, let's not forget that is the combined experience of about ten years and that is the first time that kind of a volume has been gotten out, so don't get jealous of the Blue Cross

plans. They do have this big volume out just now but as a matter of fact that volume has not been possible until just this moment.

I have a feeling that I wish we could put this whole scheme not into the insurance department of the state. I think the emphasis is wrong when it is put into the insurance department. I am sure of the fact that in some states—Michigan particularly I think had its difficulties with this question and California had a notable difficulty—they could not get their plan under a welfare program. I would rather see it under a welfare program whenever possible. You will not be bothered under a welfare program, if the state laws permit it at all. In Missouri you would not be bothered with a \$25,000 initial deposit. You would not be bothered by the actuarial restrictions the accounting restrictions that are implied in an insurance scheme. You can run this on a very much less expensive basis if it can be put under one of the welfare departments of the state, perhaps even under the state department of health in some form or another through the creation—in many states at least—of a subsidiary company of some kind. I have been afraid of the insurance patronage or control by the insurance department of the state for some of the reasons already indicated in Dr. McCann's presentation.

Many of the great drawbacks in costs have been because we have tried to give service in the costliest phases of medical care. One of the principles in hospitalization insurance has been to try to reduce the high costs of hospitalization by plans that are lower. They have left the hospitals to keep their own admission policies and that has had the effect of equalizing the high cost in some hospitals by the lower cost in other hospitals. In some way or another I think the plans might have been more successful if the high costs of surgical and medical care had been diluted the wise way by the lower cost of medical care given by the internist and by others who will not require the type of costly equipment that surgery requires.

MR. A. M. SIMONS, Chicago. The most encouraging thing today was Dr. McCann getting down to brass tacks and telling where you make mistakes. In great social experiments there is no other way to proceed.

DR. GEORGE H. KRESS, San Francisco. The Michigan State Medical Society and the California Medical Association have had similar experiences. We started out along somewhat different lines. They were much wiser than we in that they went in from the very beginning on a partial coverage plan. We went in on our idealist full coverage proposition. We have practically completed our third year of operation. When we started we asked the professional members that is the doctors—more than 5,000 of our 7,000 members went into the organization—to pay \$5. It was practically an admission or registration fee. That meant \$25,000. The state medical association lent \$50,000 which made a total of \$75,000. Seventy-five thousand dollars is not a large amount of money to start anything that takes on the scope of an insurance agency and yet in one sense that is what these medical service propositions are they are expressions of the insurance principle. In California we worked out our procedure on the basis of unit values and the basic unit we used was \$2 the price of an office call. At the present time we are paying \$1.50 on the unit much to the unhappiness of a goodly number of our members and just as in Michigan there have been surrections throughout. Also in California we have had similar regrettable experiences because the men who surrect are loyal physicians as the rest of us but they get off on these trinkets. They feel that those operating the plans are not showing proper wisdom in methods of procedure.

The ceiling in California is \$3,000. That has been a subject of great discord, because many doctors cannot understand why we should have so high a ceiling. But it has been said by one or more of the speakers today unless you have a \$3,000 ceiling and make it permissible to take in a number of \$3,000 a year employees you will not be able to secure the foremen and the higher priced shop men in these industrial groups who really set the sentiment for the other wage earners. Only recently the council of the California Medical Association has been forced to modify one of its rules permitting the California Physicians' Service under the auspices of the California Medical Association, in its own judgment to set aside the \$3,000 ceiling in circumstances might indicate.

In the beginning as stated before we gave a full coverage. We are now liquidating our full coverage contracts and within six months there will be no further full compensation or full coverage contracts given by the California Physicians' Service.

We found through our three years of experience that by having what we call our deductible contracts wherein the

patient pays for the first two visits, the amount of medical service was automatically cut down from 20 per cent to a 4 per cent basis. That is a very high percentage. With the partial surgical contracts and the partial medical contracts we believe real progress will be made.

In our hospitalization work we coordinate the efforts in conjunction with the three hospitalization groups that are existing in California. In the southern California agency the same administrative and sales distribution force takes charge of the work. We haven't been able to secure the same amount of harmony in the two northern groups but in spite of all that progress has been made and the California Physicians Service is on a paying basis. It is true they still owe the California Medical Association \$48,000 but that is a very small price to put up when you think or contemplate for a moment the great danger that was impending in that state in connection with compulsory health insurance.

I might call your attention also to the San Francisco Municipal Health Organization with a coverage of some 16,000 municipal employees where they also work on a unit basis and where they run against the rocks. But by doing away with coverage for the dependents it has been possible to at last bring that unit up to par value. So these things can be worked out.

I must disagree somewhat with Father Schwitalla in believing that we must offer in the beginning a comprehensive contract, because in the very beginning—especially when members of the profession are the underwriters—the fellows who stand behind the gun to pay the bills because that is what you do when you underwrite—it is absolutely necessary to put your proposition on an actuarially sound basis.

As you know, as you bring in thousands and thousands on the partial coverage plans and build up your reserves you can increase the amount of medical service you give. Of course all of us must acknowledge that when we offer these prepayment plans and solicit in the beginning only those who are employees in groups of eight or more we have not yet reached the very lowest economic strata in income groups and that is the problem ahead. But this is true that these states that are doing this thing and carrying on this work—these constituent state associations—are missing actuarial experience and it is getting to be of a massive kind and getting to be very much worth while.

I am in full harmony with the proposal that it is time now for the American Medical Association to step in and see to it that the officials of these various medical service plans throughout the country are brought together just as this group of editors and secretaries are brought together so that it will be possible to amass the basic information that will prevent useless and unnecessary repetition of errors that some of us have made in the past. We have profited by the experience of Michigan, and we have profited tremendously by our own experience and it is a foolish ridiculous thing for any group of men any group of physicians any state association component medical society or district group to embark on this kind of enterprise and do over again all of the foolish idealistic things we are very prone to do when we take up the cudgels on behalf of an objective such as medical service for the lower income groups.

Mr. LESTER H. PERRY, Harrisburg, Pa. I might comment briefly on just one or two of the points brought out by Dr. McCann and make some suggestions for those of you who have not yet got really started. We are beginning our third year of operation and like most of the other plans we have found we have had to raise our initial premium rates. So my first suggestion would be that by careful actuarial studies set your rates as adequately as you can possibly determine in the very beginning. The second comment I have to make relates to the cooperation and coordination of the activities of a medical service plan with those of a hospital plan. We have members of our state society and members of the board of directors of the Pennsylvania Medical Service Association who are very skeptical of tying up with the hospital Blue Cross plan. They feel, as Dr. McCann mentioned that perhaps the medical plan will be taken over by the hospital plan.

In studying this situation I did find out one fact which is rather significant. In the first place I might say that in Pennsylvania we have a little more difficult problem in cooperating with the Blue Cross plan because we have five Blue Cross plans in the state whereas in many of the other states there is one. Besides that we have one rather large hospital plan which is not a Blue Cross plan. We have been cooperating with one of those plans to date and during the period of our

operation their representatives of course sold the subscriptions to our service. During that period they themselves increased their membership by over 200,000. They got 10,000 subscribers for us. Of course the question is 'Why the big difference?' One member of our board of directors feels that they sell the medical service plan only when they have to sell the medical service agreement in order to sell the hospital agreement. Whether that is true or not I don't know. Nevertheless the increase in their membership was twenty-three times the increase in ours. There are a number of other factors. One is the income limitation. The other is that in one of the large counties in that district we do not have the cooperation of the doctors and consequently have not attempted to sell in that county. In other counties we don't have what the hospital plan people think are enough participating physicians. My second suggestion would be that in cooperation with the hospital service plan if you are sure you are getting real cooperation go ahead but at the risk of being a little cynical I would say be skeptical and look the thing over pretty carefully to see that you are getting real two sided not one sided cooperation. The third point I want to make relates to the question of supervision by an insurance department. In Pennsylvania we have a two prong supervision. Our enabling act gives the insurance commissioner the right to supervise our finances and our business affairs but the secretary of health has supervision over all matters of a professional nature. That is the way we wanted it and that is the way the act was written.

Dr. NORMAN M. SCOTT, Trenton, N. J. I hesitate to say anything on our brief experience as we compare it to the experience in California or in Michigan. Nevertheless we did have the advantage of studying and observing the activities in California and in Michigan and Pennsylvania and Toronto before setting up our plan. Dr. McCann spoke of supervision by the insurance commissioner. To us that has been most valuable. We feel we can furnish all the medical knowledge that is necessary in these plans. Our great need has been for actuarial guidance. By proper approach to our commissioner of banking and insurance we had his complete sympathy on this effort. We sat down with him when we wrote our act and he pointed out to us many points to be included in our act which would protect us under the laws of New Jersey. That of course was carried back to our legal advisers and to our own groups, but before this bill of ours went into the assembly the commissioner of banking and insurance was in complete accord and sympathy with us. He does not claim he has supervision over our plan. He doesn't like the word 'supervision' but under the law he must see that we comply with the insurance laws of New Jersey. That is the only supervision he claims to have over our plan. If we should do something that was contrary to the law he would let us know. So far he has notified us of nothing except that our contracts were according to the laws.

Dr. McCann spoke of participating physicians. I think you will find that in most states you have to recognize as participating physicians any who under the laws of that state are entitled to a full medical license. We cannot segregate one group of physicians from another. If they have the prerogatives of physicians with full license to practice medicine then you must accept claims from those physicians.

The question of income limitations was a great stumbling block in New Jersey. We at first established income limitations but have since removed all income limitations. That was done for a great many reasons. In the first place you couldn't sell a plan in New Jersey you couldn't interest industry in a plan in New Jersey which was discriminatory against any group within that industrial organization. It John Jones was an ambitious employee who took advantage of his overtime promoted his own welfare industry was interested in him is an individual because by taking advantage of his overtime and opportunities he increased his income up to \$2,500 \$3,000 or \$3,500 a year whereas if on the other side of the bunch there is a kind of good for nothing the employer isn't particularly interested in him. He doesn't take advantage of his opportunities and is still making \$100 a month. That is not the type of man industry is interested in. They are interested in the welfare of their best and most progressive employees. Therefore we have given up income limitations and have placed it on a bed occupancy basis. In other words the money we pay to our participating physicians they accept as payment in full for services rendered provided they admit their patients to a hospital for semiprivate accommodations. It is determined in the physician's office how he is to accept that patient.

and he signs the admission slip to the hospital under the hospital plan. If he signs an admission slip for semiprivate care, that is prima facie evidence that he understands he is to accept our fees as complete payment for the services rendered. On the other hand if he believes this patient is of an economic status which entitles him to accept him for additional fees, he accepts him as a private patient, puts him in a private room and accepts as a credit against his bill the amount of our fee. That is done in an effort to put it in the hands of the physician.

Right now we have a tremendous group, especially of female employees who are working for \$20 and \$25 a week who would be entitled to absolute full care under an income limitation. Still their fathers, their mothers, their families are well to do people. As soon as those girls are sick, they put them in private rooms and get them day and night nurses. The doctor wouldn't understand why he is then required to accept our fee as full fee for the care of that patient. On income studies of the state we find that an income of \$3,000, which is what industry felt we should place, would include 85 per cent of our population, whereas 35 per cent of our population accept private room care in our hospitals, thus placing a larger percentage of that group in the hands of the physician to determine whether or not he shall accept them as part pay or full pay patients.

I think some of these things should be defined. We are very loose in our terms. Complete service in Michigan and in California means—I think I am correct—home, office and hospital care. Complete service in New Jersey means that as far as our contract is concerned we give a complete service. Our contract is limited to medical service rendered while a patient is in the hospital, and while the patient is in the hospital we give complete service medical and surgical. We do not think a satisfactory type of medical care can be rendered to a sick patient unless that patient has the advantage of medical consultation or unless a patient with pneumonia can be treated by an intern. Therefore we cover medical and surgical care if they are admitted to hospital and we admit them to hospital for medical and surgical lesions.

There can be no question of the advantage of affiliation with the hospital plan. It would be a tremendous expense to set up as an independent organization a sales force, an accounting force or a claims staff. Those functions are parallel in our two organizations. Their salesmen are perfectly capable of selling our contract. They know the trade as they say they know where it can be sold. They are trained salesmen. Their accountants are trained accountants and their claim men are trained claim men. I think it is a tremendous advantage to have a very close affiliation with these hospital plans on things other than medical—on the business side the promoting side. We are not promoters, we are not salesmen, we are not accountants, and we need the advantage of their actuarial experience. They know who the safe groups are. Of course, the education of the physician is one of our greatest needs. We have a county that has voted not to cooperate with us. I am sure it is because they do not understand our philosophy or what we are trying to do to protect the future welfare of the practice of medicine.

I think I speak for my board in New Jersey when I say we don't feel these plans are going to answer the problem of medical care distribution. If we took in 50 per cent of the people in New Jersey, that wouldn't answer it. Still, that is more people than would be interested in paying for this on a prepayment basis. But we can develop an agency—we have the legal authority to develop such an agency—and its administrative methods can be extended to take over any federal plan which comes into our state. It is for that reason that we administer the farm plan. I would like to see every state agency operate the farm plan because it sets a precedent. It tells the federal government 'Here is an organization that has the legal authority and the ability to administer our plans to the satisfaction of the medical profession.' This very precedent will be of tremendous value after the emergency is over if federal funds are made available for medical care, if we can bring it under our own control. I think we can. As you talk to the people in Washington they are anxious to know how they can please the medical profession, how they can get the cooperation of the medical profession. They know that no plan they may promote will be successful without the sincere cooperation of the medical profession. If we can show them that we do have the ability, that we do have the legal authority within our state to handle federal funds—which is another thing that should go into our enabling act—the authority to accept and disburse federal, state, county or municipal tax funds in payment for medical care, that

will be of tremendous value. That should go in every state act. We are lost if we don't have that authority on the state level. We have it in our act.

Briefly, what has our experience been since July? Our hospital plan went on sale in July. Our subscribers number about 5,000. We have limited our subscribers to cross sections of groups containing 100 or more employees. We haven't gone down into the smaller groups except in two or three instances where they came in 100 per cent. We don't pay for tonsils for eleven months. We don't pay for obstetrics for eleven months. We set up reserves for them. For our first three months we paid 80 per cent and announced it in advance. The 1st of October we started paying 100 per cent, and we brought up to 100 per cent the partial payments we had made to physicians before. So we are in the black. We have a surplus of about 20 per cent of our earned subscription income. We haven't had enough experience, of course, to tell what we are going to be like six months from now or a year from now. We are negotiating with some larger groups, which is one reason we have not expanded more rapidly. We would rather take in two or three larger groups and set it at that for the year, perhaps 25,000 or 30,000, enough to support our agency and study that group before expanding further. Most of our activities are limited to northern New Jersey.

There is one thing that came up here today, the dissemination of knowledge and experience. One of the greatest needs we have felt is proper accounting reports from the various plans. We get your bookkeeping statements, your financial statements but as doctors we can't add 2 and 2 and make it come out 4 when it looks like 7 or 8 or 5. We can't make sense out of a bookkeeper's statement. We have this last month completed the form for a monthly accounting report which parallels, in substance the annual report required by the commissioner of banking and insurance in all states, but brought down to a monthly basis so that it shows our actual reserves, our actual payments, actual cash on hand, which splits up our claims, our disbursements, our costs and so on. I wish every plan would work out something of that sort, and I would be glad to give you our form as it has been developed. I think it could be made a common form because our reports to the commissioner of banking and insurance are common reports.

RADIO BROADCASTS DOCTORS AT WAR

Radio broadcasts *Doctors at War* by the American Medical Association in cooperation with the National Broadcasting Company and the medical departments of the United States Army and the United States Navy will begin on December 26 at 5 p. m. Eastern War Time (4 p. m. Central War Time, 3 p. m. Mountain War Time, 2 p. m. Pacific War Time). An exception is the Chicago area where the broadcasts will be heard by transcription at 8 p. m. Central War Time Saturdays on station WMAQ.

Titles, subjects and guest speakers for the first four programs are as follows:

December 26 Give Your Blood to a Soldier the story of battle casualties, evacuation of wounded and the use of plasma.
Guest speaker Major Gen. James C. Magee Surgeon General United States Army

January 2 Nurses at Home and Abroad the story of the army nurse and the nursing situation in home communities.
Guest speaker Capt. Ida M. Drimelison Army Nurse Corps Director of Nurses Sixth Service Command United States Army

January 9 Men Who Die in Van important factors in industrial health.
Guest speaker Dr. Stanley J. Seeger chairman American Medical Association Council on Industrial Health

January 16 Stand By for Casualties the doctor in the Navy.
Guest speaker Rear Admiral Ross T. McIntire M. C. Surgeon General United States Navy

Titles and subjects will be announced in advance in *THE JOURNAL*. Names of local stations should be ascertained from local newspapers. The National Broadcasting Company, which formerly operated the Red and Blue networks, now has only one network, which is known as the National Broadcasting Company. The Blue Network is now independent of the National Broadcasting Company. *Doctors at War* can be heard only over the network of the National Broadcasting Company.

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Bill Introduced—H R 7856, introduced by Representative Randolph, West Virginia, a bill to provide for the registration of births in the District of Columbia that were not registered when the births occurred in the District

Changes in Status—H R 7522 has passed the House and Senate, a bill to amend the District of Columbia appropriation act, 1943, so as to authorize the use of public school buildings in the District of Columbia as and for day nurseries and nursery schools H R 7781 has passed the House and Senate, a bill defining the real property exempt from taxation in the District of Columbia Buildings belonging to and used in carrying on the purposes and activities of the Medical Society of the District of Columbia will be specifically exempted from taxation, as will be hospital buildings belonging to and operated by organizations organized not for profit

MEDICAL BILLS IN CONGRESS

Bill Introduced—H R 7830, introduced by Representative Izac, California, proposes to authorize the Secretary of the Navy to construct and the President of the United States to present to the people of Saint Lawrence, Newfoundland, on

behalf of the people of the United States, a hospital or dispensary or other memorial as a token of appreciation of the action of the people of Saint Lawrence in saving the lives of officers and men of the United States ship *Pollux* and the United States ship *Truxton*, wrecked near Saint Lawrence in 1942

Changes in Status—S J Res 140 has been reported to the House, granting permission to Hugh S Cumming, Surgeon General (retired) of the United States Public Health Service, to accept certain decorations bestowed on him by the republics of Colombia, Haiti and Chile S 2769 has passed the Senate and House, a bill to authorize the rank of rear admiral in the Dental Corps of the United States Navy H R 6730 has been reported to the Senate, a bill to prohibit interstate commerce in dentures in violation of state and territorial laws This bill was passed over when reached on the Senate calendar, December 11 H R 7633 has passed the House and Senate, a bill to increase the pay and allowances of members of the Army Nurse Corps and to provide for the inclusion in the Medical Department of the Army of such female dietetic and physical therapy personnel as the Secretary of War may consider necessary

MEDICAL ECONOMIC ABSTRACTS

MEDICAL AND DENTAL CARE BY STATE AGENCIES

The great expansion in recent years of medical care by state agencies is described by Joseph W Moutin, Assistant Surgeon General, and Evelyn Flook, United States Public Health Service, in the August 21 issue of *Public Health Reports* Medical care programs 'include those offering treatment for either acute or chronic illnesses, irrespective of whether general or highly specialized medical or surgical care may be involved'

Eight departments of state governments are listed by name with the miscellaneous classifications of 'others' as participating in such medical care programs Every state and territory has one or more departments so engaged The principal classifications of such care include general medical care of the needy, services for crippled children, cancer service, pneumonia service, and prevention and care of blindness

General medical care is most frequently provided by departments of welfare and state university hospitals, "although hospital commissions, independent state general hospitals and health departments also function for this purpose in certain jurisdictions As a rule, the medical care afforded is not organized as a distinct and separate entity but is merely allowed for as one item of a generalized public assistance program which also includes provision for food, shelter and clothing"

A wide variety of plans are in operation often within a single state

Physicians may be compensated according to a set fee schedule, they may be employed on a full or part time salary basis, or there may be in operation some sort of scheme whereby a central fund is built up from periodic contributions of those covered by the plan Rates are sometimes determined by the state and sometimes by the local community Usually the medical care contemplated is that which might be given by a general practitioner in his office, plus emergency surgery Service is sometimes restricted to professional ministrations and sometimes extended to include drugs and supplies Finally, economic eligibility for service is defined in such varying terms as 'clients of general relief,' 'medically indigent,' 'those unable to pay privately for needed care,' and 'wards of the state' One state facility goes so far as to designate actual income limits, while other governmental units of the same state offer similar medical service under more general economic restrictions Residence requirements also reflect the individuality of states and even of their subdivisions"

Owing to the "multiplicity of practices, it is difficult for a state agency to maintain supervisory control over local systems of general medical care" Thirty-six states participate in the provision of general hospital care on either a free or part pay basis for needy patients Eight of these states supply the services through state operated hospitals exclusively Some states provide hospital care wholly at state expense In others, county and state share expenses Iowa, Louisiana and the District of Columbia operate a fleet of ambulances for free transportation to and from the state hospital The arrangements for special services such as for crippled children, cancer service, pneumonia and prevention and care of blindness vary widely from state to state

Most state departments of health give some attention to dental health Some complete dental health programs embrace both children and adults, but the attention of state health departments is usually confined to children's dentistry and education measures The dental activities are being quite rapidly extended, seven new departments having entered this field of activity during the last two years Most states give some sort of dental service in school systems Some state health departments operate "healthmobiles" or dental trailers which constitute motorized dental clinics In other states traveling health department dentists set up temporary clinics in a room of the school being served

It is estimated that "two thirds of the \$285,715,800 expended for composite state health services is charged to health programs which, primarily, are identified with maintenance of facilities for correction or care of mental and physical disabilities Expressed otherwise over 190½ million dollars are disbursed annually by agencies of state government for health activities in which medical or custodial care is the preponderant component This figure, it will be recalled, is exclusive of medical benefits paid through workmen's compensation channels and of expenditures for tuberculosis and venereal disease, which also involve a considerable amount of medical care The amount of expenditures varies directly according to the health of the states The hospitalization for mental disorders alone accounts for nearly \$145,000,000 Owing to the combination of various agencies it is difficult to give exact financial facts, and it is believed that the amount reported as being charged to medical care is extremely conservative This includes the cooperation of state university hospitals, general laboratory services for pneumonia control, and certain measures in cancer control and the prevention of blindness

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

State Medical Board Election—Dr Percival Dolman San Francisco was recently elected president of the state board of medical examiners to succeed Dr Fred R DeLappe Modesto Dr George Thomason Los Angeles, was named vice president and Dr Charles B Pinkham San Francisco was reelected to serve his thirtieth year as secretary treasurer of the board

Baby Blood Bank—The Irwin Memorial Blood Bank of the San Francisco County Medical Society has adopted a new service a baby blood bank consisting of half pint bottles of specially prepared baby-strength blood which are being made available to infants requiring transfusions in the San Francisco Bay region hospitals The plan was started to conserve blood and to provide a higher quality service to infants *California and Western Medicine* states that formerly when the adult size full pint bottle of blood was furnished to babies about half the blood was not required and was often wasted and furthermore, the anticoagulant concentration of sodium citrate used in adult transfusions was not always entirely satisfactory for babies The new special half pint bottle with a lower anti-coagulant concentration is found to be just right for infants it was stated

COLORADO

Society News—The El Paso County Medical Society was addressed at the Camp Carson Base Hospital, November 13 by 1st Lieut Col Philip S Hensch on 'Management of Chronic Arthritis'—Dr Lynn J Lull, Denver, showed a motion picture on syphilis before the Fremont County Medical Society in Canon City November 23 Dr Vardry A Hutton, Florence who has retired from active practice was elected an honorary member of the society at this meeting

CONNECTICUT

New Million Dollar Hospital—The dedication and formal opening of a new addition to the Hospital of St Raphael New Haven, took place October 24 According to the state medical journal the structure representing an expenditure of \$2,000,000 is essentially a complete new hospital for all patients will be cared for in the new building while the present structure will be left for service purposes The new hospital is six stories high in the middle section with corresponding wings of four and five stories each on either end On the first floor are the administrative, library and pediatric departments On the upper floors are private rooms and wards of two to six beds diet kitchens and utility and retiring rooms The surgical division includes six operating rooms with the most recent type of air conditioning The main kitchen storerooms and utility rooms are housed in the basement which also includes a coffee shop for the staff and visitors In the main reception hall is hung a recent portrait of Dr William F Verdi chief surgeon of the hospital, painted by Deane Keller, New Haven and a gift of Mr George Dudley Seymour, lawyer, New Haven

DISTRICT OF COLUMBIA

Anniversary Meeting of District Society—The Medical Society of the District of Columbia held a special program December 9, to commemorate its one hundred and twenty-fifth anniversary Dr A Magruder MacDonald president of the society gave the introductory remarks Dr Arthur C Christie past president of the society spoke on 'Medicine in the Nation's Capital 1817-1942' and Dr Frank H Lahey Boston formerly president of the American Medical Association, 'American Medicine's Contribution to the Nation'

Latin American Visits United States—Dr Miguel E Bustamante director of the Institute of Public Health and Tropical Diseases of Mexico City, arrived in Washington November 11, at the invitation of the Department of State for a two months visit to scientific and research centers in this country His trip will take him to the National Institute of Health, Bethesda Md Vanderbilt University, Nashville Tenn, Department of Biology, University of Chicago, Rockefeller Institute Laboratories in New York health organiza-

tions in rural Minnesota, Rocky Mountain Spotted Fever Laboratory at Hamilton, Mont, and the department of tropical medicine of Tulane University of Louisiana School of Medicine, New Orleans

FLORIDA

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in Florida is required by law to register annually on or before January 1, with the secretary of the state board of health, and at that time to pay a fee of \$1 A licensee failing to register annually is liable to a fine of not more than \$50

Dr Griffiths in Charge of Health Unit—Dr Thomas H D Griffiths, who until his recent retirement was chief quarantine officer of Puerto Rico and the Virgin Islands with headquarters in San Juan is now health director of the consolidated health unit in Dade County in Miami Dr Griffiths was connected with the U S Public Health Service for a number of years

Activities of State Council for the Blind—At a recent meeting in Tampa of the advisory committee for the Florida Council for the Blind the members voted to give their services without remuneration for the duration of the war or until such time as a single consulting ophthalmologist can be employed by the council and they agreed to invite other ophthalmologists to advise and assist the council on a volunteer basis It was also agreed that the members of the state medical and dental associations be requested to provide general physical and dental examinations without charge, the council to assume responsibility for payment of the cost of material used It further decided at this meeting to divide the state into three sections, the members to assume responsibility for expansion of the medical features of the sight conservation program in their respective districts Plans were also formulated to obtain eye examinations and corrective medical or surgical treatment for the needy residents of the state

ILLINOIS

Special Society Elections—Dr Joseph A Fisher, Metropolis was chosen president of the Southern Illinois Medical Association at its sixty eighth annual meeting in Marion November 5, and Dr Willis I Lewis Herrin was elected secretary-treasurer Anna was selected as the place of meeting of 1943—Wellington P Shahan Springfield executive secretary of the Illinois Tuberculosis Association was elected president of the Illinois Public Health Association during its recent annual meeting in East St Louis Clarence W Klassen, B S, Springfield, chief sanitary engineer of the state department of public health was chosen vice president and Dr Edward A Piszcsek, Chicago health officer of the Cook County health unit, was made secretary-treasurer

Chicago

Another Hotel Quarantined for Venereal Disease—The city department of health quarantined the Harmonia Hotel, 3000 Indiana Avenue December 10 on a charge of being a source of venereal infection among both civilians and men in the armed forces Thirty regular residents of the hotel were enjoined from leaving the premises by the quarantine newspapers reported Sixty-one cases of venereal infection have been traced to the hotel in recent weeks it was said

Branch Meetings—Dr Milton G Potter, Buffalo, discussed 'Management of Breach Deliveries with Practical Demonstrations' before the Englewood Branch of the Chicago Medical Society on December 1 At a meeting of the North Side Branch, December 3, Capt William E Eaton medical director U S Navy spoke on 'Medical Service in the Destroyer Force' and Major Thomas Donald McCarthy, M C U S Army 'Hawaii Before, During and After the Attack on Pearl Harbor'

Meeting on Industrial Medicine and Surgery—The Central States Society of Industrial Medicine and Surgery devoted its midwinter scientific session in Chicago December 11, to war surgery and allied subjects Among the speakers were

Dr William R Cubbins Compound Injuries
Dr Harold C Voris Head Injuries
Dr Iulo F Volini Sulfon Drug Therapy
Dr James J Callahan Demonstration of Cases
Dr Raymond W McNeely Vascular Injuries in Reference to War
Dr George L Apfelbach, Contaminated Wounds with Gas and Tetanus
Dr Milton H Kronenberg The Problem of Nutrition in Industry
Harold A Hooper DDS Mouth to Mouth Absenteeism
Dr Hedwig S Kuhn Hammond Ind Visual Testing in Industry
Major William J McConnell War Department Hygiene Supervision of Ordnance Plants

The dinner session was addressed by Colonel Norman T Kirk, M C U S Army on 'War Surgery'

Society News—Dr Wilber L. Post will deliver the presidential address before the Institute of Medicine of Chicago January 22, at the Palmer House on "The Problems and Management of Bright's Disease from the Vantagepoint of a Clinician Over a Period of Forty Years." The Chicago Society of Internal Medicine will be addressed, December 21, at the Drake Hotel in a joint session with the clinical section of the Chicago Heart Association. The speakers will be Drs. Gertrude Filits and Maxwell C. Gilbert on "Study of the Clotting Mechanism by the Response to Heparin." Drs. Louis A. Katz, Allan M. Goldman, Richard Langendorf, Louis G. Kaplan and Samuel I. Killum, "The Diagnostic Value of the Electrocardiogram Based on an Analysis of 149 Autopsied Cases," and Dr. George L. Wikkelin, Clarence A. Johnson, Ph.D., Edwin L. Smith, Ph.D., Woodrow G. Moss, M.S., Dr. Milton L. Goldberg, and James R. Wren, B.S., "Treatment of Experimental Renal Hypertension."

MINNESOTA

Physician Elected to Congress—Dr. Walter H. Judd, Minneapolis, was recently elected representative from the Fifth Minnesota District to the Congress of the United States. Dr. Judd has been a missionary in China for many years and more recently has been stationed at Fenchow Shensi. He graduated at the University of Nebraska College of Medicine, Omaha, in 1923. Dr. Judd was one of seven Americans who at a meeting of the American Bureau for Medical Aid to China on October 27 received a medal of honored merit for wartime services to China.

Four Counties Accredited for Tuberculosis Control—Stevens County was recently accredited for human tuberculosis control, making the fourth county in the state to be so classified in the cooperative program of the state medical association and the state department of health to accord counties showing a tuberculosis mortality rate not to exceed 100 per hundred thousand of population and an incidence of tuberculous infection among seniors in high school not to exceed 15 per cent. Lincoln County was accredited on Dec. 11, 1941. Olmsted County on May 22 and Murray County on August 28. The mortality rate must be based on a five year average and the student rate on tests of at least 80 per cent of the senior students of the county.

MISSOURI

Dr. Graham Receives St. Louis Award—Dr. Louis A. Graham, Bisby professor of surgery, Washington University School of Medicine, St. Louis, was presented with the St. Louis Award, November 5 during special ceremonies in the mayor's office. The award is given annually by an anonymous donor to the St. Louisan credited with the most outstanding contribution to the community during the year and includes a \$1,000 check and a certificate. According to the *St. Louis Globe Democrat*, the certificate cited Dr. Graham for his basic achievements in developing pulmonary and hepatic surgery, his productive leadership as a teacher of students and practitioners and for his influence on surgical theory and practice and in particular for his "comprehensive focusing of present knowledge on the treatment of war injuries thereby making this information easily available to all surgeons for the conservation and rehabilitation of the victim of the carnage of war." Dr. Graham was born in Chicago and graduated at Rush Medical College in 1907. He has been professor of surgery at Washington University since 1919.

NEW JERSEY

Acting Executive Officer Appointed—Edith L. Madden, office manager of the Medical Society of New Jersey, Trenton, has been appointed by the trustees as acting executive officer until an executive officer is selected to succeed the late Dr. Le Roy A. Wilkes, Trenton.

State Society Occupies New Home—The Medical Society of New Jersey has recently moved its offices into the former home of Mrs. Ferdinand W. Roebbing, 222 West State Street, Trenton. The offices are located on the left side of the first floor and consist of a reception office in which the files, membership records and working equipment of the office manager, editorial secretary and secretary to the executive officer are kept. The adjoining room formerly the library is the board room and journal office. The former solarium at the rear of the board room is the executive officer's private office. The other side of the first floor is at present being renovated and will be occupied by a local ophthalmologist when finished. The second and third floors of the building consist of bachelor apartments. The exterior of the building is of white stucco.

NEW YORK

Students and Teachers Cooperate in Control Program for Influenza Vaccine—Students and teachers at Cornell University Ithaca recently cooperated in a two week experiment under the direction of the Army Influenza Commission to test new vaccines. Drs. Norman H. Plummer and Herbert K. Linsworth, both of New York, directed the experiment.

Report of Commission on State Hospitals—For the first time in fifty years since New York State assumed care of the insane, the rate of increase of patients in residence in civil state hospitals has decreased, according to a report of the Temporary Commission on State Hospital Problems, appointed by Governor Lehman. Certain recommendations which the commission made and which have already been carried out account for the decrease. When appointing the commission, Governor Lehman stated that the annual increase had averaged 2,392 a year for the last ten years. The commission reported a drop in this number to 726 between July 1, 1941 and July 1, 1942 adding that for the four month period between July 1 and Nov. 1, 1942 there was an actual decrease of 78 patients. The report stressed as chief factors in this decrease the increased and earlier use of parole, the boarding out of large numbers of carefully selected patients in family homes and progress in testing and using new methods of shock treatment. The commission's work to date was done from appropriations aggregating \$110,000 for general expenses and for additional professional assistance in putting its recommendations into effect in the state hospitals. The report listed the following subjects as still in need of study: the system of records and reports in regard to patients' admissions, the bearing of syphilis control measures on the future population of state hospitals, research as to possible relationships of inadequate nutrition to mental illness and vocational training adjustment and employment of patients after parole or discharge.

The annual increase in the resident population of the state hospitals for the ten years July 1, 1930 to July 1, 1940, averaged 2,392 a year. The per capita cost of maintenance of patients in the state hospitals for the year ended June 30, 1941 (not including construction costs) was \$386.45. Of the 3,710 reduction in resident population, 231 represented patients transferred to family care who were still being maintained by the mental hygiene department. This leaves 3,479 as the actual reduction in numbers of patients to be maintained by the state. The maintenance of 3,479 patients at \$386.46 a year amounts to \$1,344,494.34. The average cost of building new state hospitals (before it became impossible to build them at all) was about \$4,000 per bed. To construct buildings for an additional 3,710 patients the number of which exceeds the census of each of several existing state hospitals at \$4,000 per bed, would amount to \$14,840,000. This cost is actually postponed or avoided indefinitely to the extent that the reduction of 3,710 patients in the state hospital census can be maintained. The annual budget of the state department of mental hygiene and the state institutions for the insane, mental defectives and epileptics is one of the largest of the state departments approximating \$34,487,000 and for the state hospitals alone about \$28,000,000 a year.

New York City

Dr. Conboy Named Chief Examiner for Board of Education—Dr. John E. Conboy has been appointed provisional chief medical examiner of the board of education until such time as a test is held to fill the vacancy created by the retirement in 1941 and death of Dr. Emil Altman, Sept. 11, 1942. The test will not be held until after the war.

Course on Industrial Medicine—The New York Post-Graduate Medical School announces a course on industrial medicine, January 11-15 under the direction of Dr. Harry J. Johnson. The course will be conducted by physicians in industrial medical practice in cooperation with the faculty of the medical school. Additional information may be obtained by addressing the director of the New York Post-Graduate Medical School, 309 East 20th Street.

Josiah Lilly Honored—The New York Branch of the American Pharmaceutical Association held a dinner at the Hotel Pennsylvania, December 9, in honor of Josiah K. Lilly, Ph.D., Indianapolis. The Remington Medal was presented to Mr. Lilly at the dinner (*THE JOURNAL*, November 7, p. 777). Mr. Lilly is the twenty-first recipient of the Remington Medal. He was a student of Prof. Joseph P. Remington and graduated at the Philadelphia College of Pharmacy in 1882. He is 81 years of age.

Central Agency Urged for Advising Mothers—On December 5 Mayor La Guardia's committee on wartime care of children reported that an immediate major need was a central organization but decentrally operated service for advice

and information where mothers employed in industry or about to be so employed may get definite information on facilities available for the care of their children. It was further recommended to the mayor that the proposed service also provide agencies to mothers seeking advice as to whether they should go into wartime industry on either a full time or part time basis. According to the *New York Times* the report suggested that at least six of these centers be set up as a beginning and informed the mayor that "a quick sampling study of blocks throughout the city" would be undertaken at once to get reliable information on the extent of the need for additional nursery school facilities required for the child care program suggested by the mayor when the committee was organized in his office in October (*THE JOURNAL*, November 14 p 852). The committee will function in cooperation with all private educational social and civic agencies in the areas served. It was also stated that there is a possibility that some private funds might be available for the information center program on an experimental basis.

OHIO

Changes in Health Officers—Dr Kenneth E. Bennett, Strasburg, has resigned as health officer of Tuscarawas County to enter the U S Army Air Corps. Dr Burt A. Marquand, Dennison, will continue as health officer of Atchison until Jan 1 1944.—Dr Robert A. Evans, Columbus, has recently been appointed health officer of Franklin County.—Dr Harold F. Minshull, New Lexington, coroner of Perry County, has been chosen health officer of the county, succeeding the late Dr Frank J. Crosbie, New Lexington.

Dr Hoerr Named Visiting Professor at University of Southern California—Dr Normand L. Hoerr, Henry Willson Payne professor of anatomy and director of the department at Western Reserve University School of Medicine, Cleveland, has been appointed visiting professor of neuroanatomy at the University of Southern California School of Medicine, Los Angeles. According to *Science* he will be in residence in Los Angeles until February 1. While there he will conduct a course in human neurology and give several special lectures in southern California.

Academy States Position on Medical Service Plan—In a recent statement to the press, the Academy of Medicine of Cleveland announced that the Cleveland Medical Service Association plan does not have the sanction or approval of the academy and further that the plan is a privately operated enterprise with legal rights but no academy supervision. At a regular meeting of the board of directors of the academy, November 10, a special committee was appointed to draft a statement explaining the academy's relation to the medical service association. The release to the press was prefaced with a statement that medical insurance plans were voted down by the membership of the academy after four years of intensive study. The Cleveland Medical Service Association plan was incorporated when some members of the academy assumed leadership in drawing up such a plan for citizens of Cuyahoga County (*THE JOURNAL*, July 25, p 1034) after a recent vote of the academy had rejected the approval of such a plan. Later an organization was set up in Cleveland to develop opposition to medical service insurance plans in the community which bears the name Association for Preservation of the Present American System of Medical Practice (*ibid*, August 29, page 1516). On November 17, at a special meeting of the board, the special committee which drafted the statement on medical service plans was reorganized to include three members nominated by the Association for the Preservation of the Present American System of Medical Practice, three members to be nominated by the Cleveland Medical Service Association and a chairman to be selected by these six members, all of whom are to be voting members of the Academy of Medicine of Cleveland.

SOUTH CAROLINA

University News—The Medical College of the State of South Carolina, Charleston, has announced that Andrew J. Geer, a drug wholesaler of Charleston, had established a \$1,000 scholarship in pharmacy at the college to be awarded to some student who otherwise would be unable to pursue the course.

TENNESSEE

Personal—Howard D. Schmidt, B.E., director of the division of sanitary engineering of the state department of public health, Nashville, has resigned to accept a position as principal sanitary engineer at the Institute of Inter-American Affairs for work in South America, newspapers reported November 26. Mr. Schmidt received his degree in engineering at Ohio State University, Columbus, Ohio.

Dr Sachs Delivers Haggard Lecture—Dr Ernest Sachs, professor of clinical neurological surgery at Washington University School of Medicine, St. Louis, delivered the William D. Haggard Memorial Lecture at Vanderbilt University School of Medicine, Nashville, November 27. His subject was "The Essential Qualities of a Great Surgeon." The Haggard lecture was established last year by the Vanderbilt chapter of Alpha Kappa Kappa in memory of Dr. Haggard, who was an alumnus of the fraternity and professor of surgery and clinical surgery on the Vanderbilt faculty at the time of his death.

UTAH

New Professor of Obstetrics—Dr Adelbert L. Dippel, associate professor of obstetrics and gynecology at the University of Minnesota Medical School, Minneapolis, has been named professor and head of the department of obstetrics and gynecology at the University of Utah School of Medicine, Salt Lake City. Dr. Dippel graduated at the University of Texas Medical Branch, Galveston, in 1928. For a time he served on the staff of Johns Hopkins University School of Medicine, Baltimore, and has been a member of the faculty at Minnesota since 1940.

GENERAL

Association for Advancement of Science Postpones Meeting—The meeting of the American Association for the Advancement of Science and forty-four of its affiliated and associated societies that was scheduled to be held in New York beginning December 28 has been postponed in compliance with a direct request of the Office of Defense Transportation.

The President's Birthday Again Approved for Collection of Poliomyelitis Funds—President Roosevelt has again approved the public celebration of his birthday in January for the purpose of collecting funds for the National Foundation for Infantile Paralysis. In a letter to Mr. Basil O'Connor, New York president of the foundation, President Roosevelt stated that he felt that any "interruption in this work would be extremely inadvisable unless absolutely necessary."

Social Hygiene Day—The annual observance of social hygiene day has been announced for February 3, according to an announcement from the American Social Hygiene Association, New York. A pamphlet entitled "Social Hygiene Takes Battle Stations" contains suggestions for community programs and gives an outline of the national social hygiene movement. The American Social Hygiene Association and its one hundred forty-five affiliated social hygiene societies and committees cooperate with other national state and local voluntary organizations in the aim to curb and reduce venereal diseases. The new brochure states that during the first world war there were 157,146 more new cases of syphilis and gonorrhea among United States soldiers, sailors and marines than there were wounds in battle itself. Total absences from duty due to this cause kept the equivalent of 20,600 men out of the fighting for a whole year.

Dr Lyght Named Director of Health Education of Tuberculosis Association—Dr Charles E. Lyght, since 1936 professor of health and physical education for men and director of the college health service, Carleton College, Northfield, Minn., has been appointed director of health education of the National Tuberculosis Association. He succeeds Dr. Harry E. Kleinschmidt, New York, who resigned last summer. Dr. Lyght has served for the last five years as chairman of the Tuberculosis Committee of the American Student Health Association. He is widely known as a lecturer on public health subjects and has contributed to many medical educational and lay journals in the fields of tuberculosis control, student health and clinical medicine. In 1926 he graduated at Queen's University Faculty of Medicine, Kingston, Canada. In 1927 he joined the faculty of the medical school of the University of Wisconsin, Madison, as assistant professor of medicine. Dr. Lyght was also connected with the department of student health of the university, becoming chief physician in 1932 and director in 1936.

Winners of Mead Johnson Awards—Drs. Howard A. Howe and David Bodian, who have been pursuing studies in poliomyelitis for several years, were presented with a prize of \$500 during the annual meeting of the American Academy of Pediatrics in Chicago in November. A prize of \$300 went to Dr. Harold E. and Helen C. Harrison, Ph.D., New Haven, for their painstaking work on the excretion and absorption of phosphate by the kidneys. The prizes are known as the E. Mead Johnson Awards for Research in Pediatrics and are presented through the American Academy of Pediatrics. The prizes just awarded were for the year 1941. Drs. Howe and Bodian will continue their studies on poliomyelitis at Johns Hopkins University School of Medicine, Baltimore, where, under a recent grant from the National Foundation for Infantile Paralysis, a Center for the Study of Infantile Paralysis

and Related Viruses is being set up under the direction of Dr Kenneth F. Mancy (THE JOURNAL, August 1, page 1121). Both Dr Harrison and his wife are on the faculty of Yale University School of Medicine.

Changes in Industrial Hygiene Foundation—The Industrial Hygiene Foundation, New York, elected the following members to its board of trustees at the seventh annual meeting in Pittsburgh, November 10-11. Ned H. Denborn, Ph.D., executive vice president and managing director, National Safety Council, Chicago; Philip Drinker, Clinical professor of industrial hygiene, Harvard School of Public Health, Boston; Lieutenant Colonel Anthony J. Lunz, M.C., U.S. Army, chief, Occupational and Military Hygiene Subdivision, Preventive Medicine Division in the Division of Industrial Health, Office of the Surgeon General; Dr. Clarence D. Selby, Detroit, medical consultant, General Motors Corporation. Other board members were re-elected. The foundation also announced the recent appointment of John F. McMahon, executive secretary, as managing director of the foundation to succeed Harry B. Miller, Sc.D., Pittsburgh, who retired from active management because of ill health. Dr. Miller continues as consultant. Dr. Raymond Huxley of the Maryland State Industrial Accident Commission, Baltimore, was named to the medical committee of the foundation.

New Gorgas Medal Awarded to Military Physicians—Three military physicians were presented with the first awards of the newly established Gorgas Medal at the Cosmos Club, Washington, D.C., December 15, according to an announcement by the Association of Military Surgeons of the United States. They are Brig. Gen. Jefferson Randolph Keen, M.C., U.S. Army, Washington, D.C.; Brig. Gen. Frederick F. Russell, M.C., U.S. Army, Boston; and Rear Admiral Edward R. Stitt, M.C., U.S. Navy, Washington, D.C., all retired. The awards were established recently by John Wyeth and Brother, Inc., Philadelphia, in memory of Surg. Gen. William Gorgas, whose work in preventive medicine made possible construction of the Panama Canal. The awards include large silver medals inscribed with a likeness of General Gorgas and individual checks for \$500. The medal will not be an annual award but will be presented only when such recognition is voted by the association. According to the announcement, General Keen was cited for his aid in conquering yellow fever by initiating warfare in Cuba against mosquitoes in 1900. General Russell for first immunizing the entire army and reducing the typhoid peril to a minor problem and Admiral Stitt for extensive research and writing on tropical maladies and their prevention. The medals were presented at special ceremonies at which Mrs. Aileen Wrightson, daughter of General Gorgas, was guest of honor and received a courtesy medal. The presentation followed introductory remarks by Frank F. Law, head of John Wyeth and Brother.

Fellowships in the Medical Sciences—Fellowships in the medical sciences similar to those which have been administered by the Medical Fellowship Board of the National Research Council since 1922, will again be available for the year beginning July 1. These fellowships supported by grants from the Rockefeller Foundation to the National Research Council, are designed to provide opportunities for training and experience in research in all branches of medical science. They are open to citizens of the United States or Canada who possess an M.D. or a Ph.D. degree and are intended for recent graduates who are not yet professionally established. In addition to these fellowships the Medical Fellowship Board administers two groups of research fellowships, made available through a grant from the National Foundation for Infantile Paralysis, Inc. The first group, open to applicants who hold either the Ph.D. or the M.D. degree is for the purpose of providing opportunities for special training and experience in the study of filtrable viruses. The second group open only to graduates in medicine who have completed one or more years of hospital experience in clinical surgery and are planning a career in orthopedic surgery, is designed to provide opportunities for training and research in those basic medical sciences which will be of particular value in furthering progress in the field of orthopedic surgery. Fellows will be appointed at a meeting of the Medical Fellowship Board late in February. Applications to receive consideration at this meeting must be filed on or before January 1. Appointments may begin on any date determined by the board. For further particulars concerning these fellowships, address the secretary of the Medical Fellowship Board, National Research Council, 2101 Constitution Avenue, Washington, D.C.

Plan to Improve Teaching of Tropical Medicine in Medical Schools—The John and Mary R. Markle Foundation has given \$25,000 to the Association of American Medical Colleges to finance a program for the improvement

tropical medicine in the medical schools in the United States and Canada. Under the plan, each medical school will be offered an opportunity for two members of its teaching staff to attend a two month course in tropical medicine beginning January 4. The development of the program will be in charge of a committee on tropical medicine of the association consisting of Drs. Henry E. Meleney, Herman M. Biggs, professor of preventive medicine, New York University College of Medicine, New York; chairman, Malcolm H. Soule, Sc.D., professor of bacteriology and head of the department, University of Michigan, Ann Arbor; and Dr. Hiram W. Kostmayer, acting dean, Tulane University of Louisiana School of Medicine, New Orleans. The Surgeon General of the Army has given permission for one representative from each school to attend the course in tropical medicine being given to medical officers at the Army Medical School, Washington, D.C. The course consists of a broad survey of tropical medicine and is intended for clinical instructors in medical schools. The department of tropical medicine at Tulane has agreed to give a special course in tropical medicine in which particular emphasis will be placed on the laboratory diagnosis, pathology, clinical aspects and prevention of tropical diseases. This study is intended particularly for physicians who will teach the laboratory aspects of tropical diseases. Each of these courses can accommodate thirty instructors from medical schools. Travel and living expenses and, in the case of the Tulane course a tuition fee, will be paid from the appropriation of the Markle Foundation. The deans of medical schools have been asked to nominate instructors to attend these courses and the response indicates that each course will have a maximum attendance. Preference will be given to the schools whose instructors are now least well prepared to teach tropical medicine.

It is recognized that there is also great need for instructors in medical schools to obtain practical experience in tropical medicine. Preliminary inquiry indicates that such experience can probably be provided in the American tropics later during the coming year. Candidates for such practical experience would be selected from among those who have completed the course at the Army Medical School or Tulane and other instructors who have had academic training but not field experience in tropical medicine.

The committee in charge of the project has also interested itself in the collection of teaching specimens and material for the teaching of parasite and other tropical diseases in medical schools. The Army Medical School with the cooperation of the National Institute of Health, Bethesda, Md., and other institutions is developing a distributing center for such material. Information concerning the center is being sent to the medical schools with instructions for the procurement of material either locally or from the center. It is expected that in addition to laboratory specimens of animal parasites, there may be available certain charts, lantern slides and motion pictures. The Office of the Surgeon General of the Army has offered to make available to medical schools information which has been collected on the distribution of tropical diseases throughout the world. Plans for editing this material are in progress, and it is expected that maps will also be prepared and made available to medical schools, showing the world distribution of the important tropical diseases. The Markle Foundation has made an appropriation of \$3,000 to the National Research Council for the preparation of this material.

CANADA

New Professor of Obstetrics and Gynecology—Dr. John Ross Vant has been appointed professor of obstetrics and gynecology at the University of Alberta Faculty of Medicine, Edmonton, succeeding the late Dr. Leighton C. Conn. Dr. Jermyn O. Baker is associate professor. All are of Edmonton.

Course on Chemical Warfare—McGill University Faculty of Medicine, Montreal sponsored a course of lectures and demonstrations on chemical warfare, October 19-30, under the auspices of the director of civil air raid precautions. Dr. Israel M. Rabinowitch, associate professor of medicine at McGill and scientific adviser on chemical warfare to the federal office of civil air raid precautions, conducted the course.

LATIN AMERICA

Blood Plasma Bank in Cuba—The American-Cuban Fund of Helping the Allies has donated a fund of \$12,500 to the Medical Federation of Cuba to establish a blood bank in Cuba. Drs. Gonzalez de Mendoza Arostegui, Havana, and Moises Chediak, Havana, were appointed by the national committee of the federation to study the organization and functions of blood banks in the United States preliminary to the establishment of the Cuban bank.

Traumatic Duodenal Ulcer

Sir Arthur Hurst, Mr. W. H. Ogilvie and Dr. C. Keith Simpson have reported in *Glasgow Hospital Reports* an example of the rare production of duodenal ulcer directly by trauma. A man aged 39 who was admitted in October 1931 had had good digestion until June 1915 when he was kicked in the epigastrium by a horse. He sustained a big bruise and was unconscious for a few minutes. Some hours later severe abdominal pain and vomiting developed. Continuous pain and vomiting after every meal prevented work. In July his appendix was removed, but on leaving the hospital he had severe pain after every meal. In October 1915 gastrojejunostomy was performed. The pylorus was found constricted by a healed ulcer. After the operation he kept fairly well for a time and returned to his work as a metallurgist. But he was always liable to attacks of pain and diarrhea. He unproved but the trouble returned each winter from 1919 to 1922 and between times he had shorter periods of ill health. In 1923 hematemesis proved nearly fatal. He improved again until May 1925 when he had another severe hemorrhage. Partial gastrectomy was performed. No ulcer was found but there was a healed scar at the pylorus which was constricted. His health improved but in the subsequent years he had at intervals serious hemorrhages in the form of melena. In July 1931 he had his tenth serious hemorrhage.

On admission he complained of epigastric pain after meals, but this could be prevented by leading a quiet life. X-ray examinations showed that the remaining portion of the stomach emptied rapidly but that some backflow took place as far as the duodenal bulb. A Pola-Moynihan gastrectomy was performed after adhesions had been divided. He made an excellent recovery. Ten years later in 1941 he was in good health and had gone to America in a technical job for the government.

This is the only case of gastric or duodenal ulcer seen by the writers in which symptoms developed immediately after a local injury. Chabrier and Desjardins (*Bull. de med.* 14:78 [July] 1923) described a case of hematemesis immediately after the kick of a horse in the epigastrium. M. J. Stewart (Hurst and Stewart, *Gastric and Duodenal Ulcer*, New York: Oxford University Press, 1929) found focal hemorrhages and laceration of the stomach in deaths from trauma which might well have been the starting point of ulcer had the patient survived. Stewart also reported that a man who was crushed in the epigastrium by the fall of a mine roof complained of pain after taking food and perforation occurred three months later. At operation there was already intense peritonitis and he died two days later. The necropsy showed an early chronic ulcer on the anterior gastric wall.

The Destruction of Instruments in the Museum of the Royal College of Surgeons

The recent publication of 'The History and Evolution of Surgical Instruments,' by C. J. S. Thompson, honorary curator of the historical collection of the Museum of the Royal College of Surgeons of England, shows the damage done by German vandalism to the greatest collection of surgical instruments, new and old, in the world. These numbered about three thousand when disaster overtook them. In one air raid a few were injured by water and the council of the British Institute of Surgical Technicians undertook their repair, but before this was completed nearly the whole of the surgical instrument museum was destroyed in another raid. From the debris some two thousand were salvaged, of which about fifteen hundred and a small collection of Chinese instruments were in fair con-

dition. The remainder, comprising most of the obstetric instruments, were badly damaged. As shown by his 'Guide to the Surgical Instruments in the Museum,' Dr. Thompson has long been in the words of the late conservator of the museum, Sir Arthur Keith, recognized at home and abroad as an authority on all that pertains to the technique used by medical men of past times in the treatment of disease. He has traced in the collection the evolution of the scalpel from the Babylonians of 1000 B. C. through the Greeks and Romans down to modern times and similarly the evolution of the imputating knife, the saw and other instruments. The rescued instruments have, after temporary refurbishing, been stored in metal cases supplied by the institute under the direction of which they will be renovated after the war by skilled craftsmen. Much of the damage of course is irreparable. Here is one phase of a war which is being waged not merely against peoples but against civilization itself by a nation which never tires of bragging about its Kultur. It is fortunate that Dr. Thompson's profusely illustrated books to some extent compensate for the loss of instruments in this great historical series.

Factory Accidents and the War

The entrance into war industries of a large part of the population has had a profound effect on factory accidents. In his annual report Sir Wilfrid Garrett, chief inspector of factories, estimates that accidents in factories cause a loss of over 50 million man hours each month and factory figures do not

Probable Accidents During Four Years

	Fatal		Nonfatal	
	Number	Increase % on Previous Year	Number	Increase % on Previous Year
1938	844		179,159	
1939	1,104	17	192,371	7
1940	1,172	24	230,607	20
1941	1,646	20	269,652	17

include mining, road and rail transport, agriculture and shipping. The health of factory workers has been well maintained which is attributed largely to provision of meals in canteens. Women have taken up war work in immense numbers. There is no indication that their health has been adversely affected. But the unwisdom of employing women who have had children on work that requires undue strain on the abdominal muscles is pointed out. As might be expected, the war has been attended with a great increase in preventable accidents. The figures for the past four years are given in the accompanying table. The increase in factory accidents to women has been much greater than in the case of men. The number of all factory accidents to adult men was 134,752 in 1938 and 191,343 in 1941, an increase of 42 per cent. The number for adult women was 14,626 in 1938 and 42,587 in 1941, an increase of 192 per cent. But the liability to accident per capita was less in women than in men. The liability for men was 1 in 25 in 1938 and 1 in 20 in 1941; the liability for women was 1 in 105 in 1938 and 1 in 56 in 1941. The great increase in the liability of women can be explained by the large number who were new to factory work.

Lord Nuffield Honored

Lord Nuffield's munificent gifts to surgery have often been reported previously. In appreciation the Royal College of Surgeons has conferred on him its honorary medal, a distinction given to only eighteen other persons in the last hundred and forty years. In making the presentation the president, Sir Alfred Webb Johnson, said that, while it was true that great riches had no real use except for distribution, it was equally true that virtue and liberality in the present possessor were the most just and indisputable titles of nobility. Lord Nuffield

replied that nothing he had ever received had given him greater pleasure. What he had done for medicine and surgery was only what he considered he should have done. Mr. Ernest Brown, minister of health, said that too often physicians who lavished money on expensive buildings showed too little concern for the men and women who were to use them. Lord Nuffield never made that mistake. Of all his gifts they would like to praise him most for two things: (1) establishing six professorships and two readerships at Oxford, (2) founding the Institute of Social Medicine.

Tuberculosis in Argentina

The Comisión Nacional de Tuberculosis was recently appointed by the government of Argentina as a branch of the National Department of Hygiene. The members of the board of directors are Drs. A. A. Rimondi, president, R. F. Vaccarezzi, vice president, and R. A. Vaccarezzi, secretary.

Dr. J. A. Friera of the Sanitary Branch of the General Department of prisons and penal institutions studied the incidence of tuberculosis among prisoners and delinquents. Among 1,893 prisoners there were 29 with tuberculosis (1.53 per cent) and 150 with diseases of the respiratory tract (7.92 per cent). Among 1,509 delinquents there were 10 with tuberculosis (0.66 per cent) and 127 with diseases of the respiratory tract (8.41 per cent). In the whole group of 3,402 prisoners tuberculosis was found in 39 (1.41 per cent) and nontuberculous diseases of the respiratory tract in 227.

Drs. A. A. Rimondi, J. Gillo and L. M. Bontante of Buenos Aires took roentgenograms of the chest of 25,000 school children and discovered tuberculosis in 2,784 children. The disease was in evolution in 1.21 per cent of the cases and inactive in 10.1 per cent.

Drs. Gumersindo Snyago and Iñás Niput of Córdoba recently observed children who had been given BCG vaccine in the Instituto de Fisiología of that city. A group of 350 newborn infants had the vaccine from March 1937 to March 1938. It was administered by mouth. It was given during the first week after birth. It was administered during fasting and dissolved in tea or milk in a dose of 0.01 mg. every other day to a total number of three vaccinations. Another group of 50 newborn infants had intradermal injections of 0.1 mg. of BCG vaccine in 0.2 cc. of a vehicle. The highest figures of allergy among infants who had the vaccine by mouth were observed from the third to the fourth months. The highest allergy figures in the second group appeared between the first and second months after the injection. The minimal figures of allergy in infants in this last group were in the fourth and fifth months. The rate of mortality in vaccinated infants was 8.3 per cent in comparison with that of 15.6 per cent in nonvaccinated infants. The highest rate of mortality in vaccinated infants occurred during the first three months of life, whereas in nonvaccinated infants it was shortly after the infants reached the age of 1 year.

The prevention of tuberculosis in Argentina has made great progress. At present all the applicants to and employees in positions in which they are in frequent contact with the public are systematically observed for tuberculosis. All government employees report for periodic examinations. All applicants for government positions have clinical examinations, roentgenograms and tuberculin tests. The allergic workers are classified. Among 10,863 applicants for work who were examined for tuberculosis, a positive diagnosis was made in 104. Fifty-one individuals were accepted to work with temporary certificates while they were under antituberculosis therapy. The group of 10,708 healthy applicants was observed for two years and tuberculosis developed in 6. Before a system of examinations was

adopted for workers, the average frequency was 520 per hundred thousand individuals, which is ten times as much as that observed at the present time.

TYPHOID IN CHILE

Dr. H. San Martín Ferrari recently studied sanitation and typhoid in Chile. He reviewed previous epidemics and some 300 cases which occurred during a recent outbreak. He concludes that the mortality from gastrointestinal infections in Chile, especially in Santiago, has increased during the last three years. Several sources of infection, including possible contamination of drinking water, are present in Santiago. The main sources of infection are green vegetables, ice cream, milk products and probably also flies. An examination of 600 samples of feces of persons handling food showed that 17 per cent were typhoid carriers.

Detoxicating Action of Ascorbic Acid in Gold Therapy

Dr. Rogelio F. Carratalá of Buenos Aires recently conducted clinical observations and experimental research on the role of hypovitaminosis C in the development of hypersensitivity to gold therapy. The method generally used to determine hypersensitivity to gold therapy is that of making an intradermal reaction with a gold preparation. The method advised by Carratalá is more simple and reliable. It consists in making light scarifications on a small area of both arms. They should not bleed. Immediately afterward those of one arm are covered with gauze soaked in a 20 per cent sodium gold thiosulfate solution and those of the other arm are covered with gauze soaked in a mixture of this solution and a 20 per cent ascorbic acid solution. The soaked gauze on each arm is left in contact with the scarifications for fifteen to twenty hours, after which it is removed and the results are read as when an intradermal test is performed. The author made observations in 6 cases of rheumatism. The results of the reaction to the sodium gold thiosulfate alone were strongly positive in 4 cases, weakly positive in 1 case and negative in 1 case. The results of the reaction to the mixture of sodium gold thiosulfate and ascorbic acid were weakly positive in the case in which the same reaction appeared to sodium gold thiosulfate alone. In all other 5 cases the results of the reaction were negative. By testing the excretion of vitamin C in the urine it was found that the 4 subjects showing hypersensitivity to gold therapy were suffering with hypovitaminosis C. The hypersensitive patients showed intolerance to the gold therapy. The symptoms were controlled by administration of vitamin C. One of the patients developed acute dermatitis in the course of gold therapy. The latter was discontinued, vitamin C was administered and gold therapy was again administered without further toxic effects.

The author experimented on guinea pigs and on the basis of his results, emphasizes the value of vitamin C in preventing intolerance and the toxic effects of sodium gold thiosulfate.

Tuberculosis in Paraguay

Dr. J. M. Boettner, a professor in the Faculty of Medical Sciences of the National University of Paraguay, wrote an article in the *Anales de la Facultad de Ciencias Médicas*, January-June, 1941, in which he stated that the city of Asunción is now in a complete epidemic phase without having reached the greatest figures of massive tuberculous infection. People in the rural zones of Paraguay are in a state of pretubercularization. They will be easy victims for epidemic outbreaks when the routes of communication with other places improve. The antituberculosis campaign is well organized in the capital of the country, however, much is lacking. There should be ready one or one and one-half beds for tuberculous patients for each death from tuberculosis which is registered. The mortality for tuberculosis in Asunción is 190 deaths for each hundred thousand persons and it represents more than 10 per cent of the general mortality.

Deaths

Hubert Work ☉ Englewood Colo, formerly Secretary of the Interior and President of the American Medical Association, died of coronary thrombosis in St Joseph's Hospital, Denver, December 14

Dr Work was born in Marion Center, Pa July 3, 1860. He studied at the Indiana State (Pa.) Normal School and Medical Department of the University of Michigan, taking his medical degree at the University of Pennsylvania in 1885. The same year he began the practice of medicine in Greeley Colo. Later he moved to Pueblo, where he was a founder in 1896 of the Woodcroft Hospital for nervous and mental diseases, serving there for many years as physician in charge. He was also superintendent of the early Woodcroft School of Feeble Minded Children.

In 1908 Dr Work was delegate at large for the Republican National Convention and subsequently served as chairman of the Colorado Republican State Central Committee and member of the Republican National Committee. In 1921 he became first assistant postmaster general of the United States. Then following one year's service as Postmaster General Dr Work became Secretary of the Interior on March 5, 1923, a position he held until July 24, 1928. The following year he was chairman of the Republican National Committee. He was once a candidate for the United States Senate but was defeated by a small majority.

Throughout his long public career, Dr Work maintained a deep active interest in medical developments. During the late eighties he was a member of the Colorado State Board of Medical Examiners. For four years he was president of the state board of health and later president of the Colorado State Medical Society. In 1906 he began his first term as a member of the House of Delegates of the American Medical Association. In 1916 he became the first chairman of the House of Delegates of the Association and later its first speaker. He was a member of the Judicial Council and in 1920 was chosen President-Elect of the Association, assuming the presidency in 1921.

Dr Work's professional reputation was obtained as a clinician and psychiatrist. He received many honorary degrees and was a member of numerous scientific groups devoted to his specialty, serving in 1911 as president of the American Medico Psychological Association. He was a fellow of the American College of Physicians and a member of the Central Neuropsychiatric Association and of the American Psychiatric Association. He was consulting physician to the Colorado Fuel and Iron Company Hospital and the Colorado State Insane Asylum, Pueblo. Twice he was chosen president of the Medical Veterans of the World War.

During World War I Dr Work rendered distinguished services acting as medical adviser of the Provost Marshal General. It was in this capacity that his diplomatic qualities were of inestimable service in correlating the work of the medical department of the army with that of the Provost Marshal General's Office. At the conclusion of the war he became a colonel in the medical reserve of the Army.

Dr Work's death closes a long and distinguished life. He was a kindly man, endearing himself to every one by his affability, calm and reserve. He inspired cooperation and efficiency and was ever ready for usefulness with kind comment or witty repartee.

HUBERT WORK, M D, 1860-1942

William Toy Shoemaker ☉ Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1891, specialist certified by the American Board of Ophthalmology, professor of ophthalmology and vice dean for ophthalmology at the Medico Chirurgical College, Graduate School of Medicine University of Pennsylvania, formerly clinical professor of ophthalmology at the Woman's Medical College of Pennsylvania, member of the American Ophthalmological Society, College of Physicians of Philadelphia and the Association for Research in Ophthalmology, Inc., fellow of the American College of Surgeons, served as consultant to the Germantown, the Pennsylvania and the Woman's hospitals, consultant and honorary chief, department of ophthalmology, Laikmanau Hospital where he was formerly an assistant ophthalmologist, chief ophthalmologist and an executive medical officer, chief department of ophthalmology, Graduate Hospital of the University of Pennsylvania served overseas as a major during World War I, a contributor to medical textbooks, encyclopedias and medical journals for five years editor of the *Annals of Ophthalmology*, aged 73, died, November 26, in the Graduate Hospital.

James T Hurd, Galeton Pa., College of Physicians and Surgeons Baltimore, 1885, member of the Medical Society of the State of Pennsylvania, past president of the Potter County Medical Society, for many years served on the school board of Galeton as a member of the board of health and as treasurer of the Potter County School Directors' Association for many years bank president, in 1940 received an award from the Seventh Council District of the Medical Society of the State of Pennsylvania for fifty years of practice, aged 83, died, November 1, of coronary thrombosis.

William Elliott Doid, Charlottesville, Va. University of the City of New York Medical Department New York, 1880, member of the Medical Society of the State of New York the American Psychiatric Association the New York Academy of Medicine the New York Society of Medical Jurisprudence and the New York Neurological Society, formerly medical superintendent of the River Crest Sanitarium, Long Island City, at one time physician to the Manhattan State Hospital and the psychiatric branch of the New York Hospital New York, aged 86, died November 9.

Arthur D Gray ☉ Topeka, Kan., Kansas Medical College, Medical Department of Washburn College, Topeka,

1912, member of the American Urological Association fellow of the American College of Surgeons, urologist, Christ's Hospital, member of the staff of Stormont and St Francis hospitals, urologist and consultant in genitourinary diseases at the Topeka Municipal Clinic, Menninger Clinic and Sanitarium, Hillcrest Sanatorium and the Atchison, Topeka and Santa Fe Railway Hospital, aged 56, died, October 30 of coronary occlusion.

Robert Edwin Hilburn, Wichita Falls, Texas, University of Louisville (Ky.) Medical Department, 1909, member of the State Medical Association of Texas served in the medical corps of the U S Army during World War I, for the past fourteen years medical examiner for the Wichita Falls area of the Civil Aeronautics Administration, aged 60, died, September 6, of heart disease at his farm home near Antelope.

Irving Emerson Sumner ☉ Brooklyn, University and Bellevue Hospital Medical College, New York, 1917 served in the medical corps of the U S Army during World War I associate surgeon at the Beth Moses Hospital and adjunct surgeon at the Wyckoff Heights Hospital, aged 48, died,

November 9 in the Long Island College Hospital of thrombosis of the heart with multiple embolism

Frank Hamlin Blackmarr ♂ Chicago, Hahnemann Medical College and Hospital, Chicago, 1897 member of the Radiological Society of North America, Inc. on the staff of the Chicago Memorial Hospital, aged 71, died September 16, of circomotosis due to carcinoma of the left middle finger

William Byrne Brown ♂ Columbia Mo., Rush Medical College, Chicago, 1930, director of the division of health education at Stephens College, past president of the Boone County Medical Society, fellow of the American College of Physicians, aged 38, died suddenly, November 8, of heart disease

Meyer Merle Cutler, Chicago, University of Illinois College of Medicine, Chicago, 1937, member of the Illinois State Medical Society formerly house physician and resident radiologist at Michael Reese Hospital, aged 31, died November 17, in Miami Beach Fla. of rheumatic heart disease

Pasquale A. Rosati, Pittsburgh, Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1900 served as a captain in the Italian Army Medical Corps during World War I, aged 71, died, October 27, in the Belvedere General Hospital of endocarditis and cardiac asthma

Herbert James Bryson, New Orleans, George Washington University School of Medicine, Washington D. C. 1907, served as a major in the U. S. Army during World War I, aged 61, died, November 3, of generalized arteriosclerosis and arterio-sclerotic heart disease

Harry Raymond Fleming, Humboldt, Sask., Queen's University Faculty of Medicine, Kingston Ont. 1922, was first elected to the House of Commons at the general election in 1935 and re-elected at the 1940 general election, aged 48, died suddenly, November 5

Benjamin Levine, New York, New York Homeopathic Medical College and Flower Hospital, New York, 1920, served during World War I, aged 53, died November 6 in the New York Polyclinic Hospital of carcinoma of the stomach with metastases to the pancreas

Lucius Barton Leake ♂ Temple, Texas, University of Texas School of Medicine, Galveston, 1924, president of the Bell County Medical Society in 1934 for many years on the staff of the Kings Daughters Hospital, aged 45 died recently of carcinoma of the colon

Clifford Reno Neare, East Orange, N. J., Jefferson Medical College of Philadelphia, 1899 member of the Medical Society of New Jersey, for many years on the staff of the Orange Memorial Hospital, Orange, aged 68, died, November 9 of heart disease

Charles William Titus, Bloomfield, N. J., College of Physicians and Surgeons, Baltimore, 1897, served overseas during World War I, aged 60, died, November 5 in the Veterans' Administration Facility, Lyons, of diabetes mellitus and heart disease

Clyde Amandee Noland ♂ Long Beach, Calif., State University of Iowa College of Medicine, Iowa City, 1905, specialist certified by the American Board of Ophthalmology, aged 67, died, October 24, in the Community Hospital of septicemia

Charles Collmar ♂ Easton, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1884, at various times a member of the city council consulting physician to the Easton Hospital, aged 82, died, November 20, of coronary occlusion

James Thomas Powell, Gravette, Ark., Medico Chirurgical College of Kansas City, Mo., 1903, member of the Arkansas Medical Society, served as health officer of Gravette, aged 79, died, October 28, of coronary thrombosis and angina pectoris

Amos Canfield ♂ New York, Cornell University Medical College, New York, 1902 president of the Tioga County Historical Society from 1934 to 1940, aged 64 died, November 13, in Candor, N. Y., of cerebral hemorrhage

Edward Robert Herman, Bloomington, Ill., National Medical University, Chicago, 1906, Illinois Medical College, Chicago, 1907, served during World War I, aged 73 died October 21, of hemiplegia and coronary sclerosis

William Henry Pollmer, Lewisburg, Pa., Hahnemann Medical College of Philadelphia, 1882, aged 83 died November 11, in the Evangelical Hospital of right hemiplegia, chronic degenerative endocarditis and arteriosclerosis

Silas Sterling Stahl ♂ Franklin, Ohio, St. Louis University School of Medicine, 1905, at one time assistant in surgery at his alma mater, served during World War I, aged 73, died, November 6, of carcinoma of the liver

Carl V. Urbom, Rockford, Ill., Hering Medical College, Chicago, 1903, member of the Illinois State Medical Society, aged 83 died, October 30, in St. Anthony's Hospital as the result of a fractured hip received in a fall

Robert Dwyer, Indianapolis, Indiana University School of Medicine, Indianapolis, 1908 member of the Indiana State Medical Association, aged 64, died, November 11, in St. Francis Hospital of cerebral hemorrhage

William Josiah Shipp, Ore. City, Texas, College of Physicians and Surgeons, Dallas, 1906, St. Louis College of Physicians and Surgeons, 1908, aged 65, died, October 16, in a hospital in Dallas of uremia

Thomas Arthur Costello, Cleveland, University of Wooster Medical Department, Cleveland, 1900, served in the medical corps of the U. S. Army during World War I, aged 69, died, October 15

Mary Ladd Bruner, Greenfield, Ind., Woman's Medical College, Chicago, 1885, for many years a trustee at Earlham College, Richmond, Ind., aged 87, died, November 6, of chronic arthritis

Wade Hampton Atkinson ♂ Washington, D. C., Georgetown University School of Medicine, Washington, 1889, aged 76 died November 14, in Johnston County, N. C., of angina pectoris

Mina Logue Fuller Peterson Brainard, Avalon, Calif., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1879, aged 86, died, October 17, of heart disease

Joseph Lane Voorhes, Columbia, Tenn., College of Physicians and Surgeons, Baltimore, 1886, formerly health officer of Maury County, aged 82, died, October 24, of heart disease

Charles R. Tanner, Henderson, Ky., University of Tennessee Medical Department, Nashville, 1901, aged 65, died, November 2 in the Henderson Hospital of myocarditis

Daniel Emmett Barnett, Homer, Ind., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905, aged 67, died, November 18, of coronary occlusion

Clarence S. Bolender, Clearwater, Fla., Eclectic Medical College of Indiana, Indianapolis, 1903, aged 80, died, November 6, of congestive heart disease and senility

Robert Lee Jenkins, Winston-Salem, N. C., College of Physicians and Surgeons, Baltimore, 1903, aged 71, died November 1, of coronary thrombosis

Mysta L. Austin Hendricks, Salem, Ore., Willamette University Medical Department, Salem, 1907, aged 61, died October 29, of heart disease

Quincy A. Sturgeon, Madrid, Iowa, Kentucky School of Medicine, Louisville, 1883, aged 83, died, October 24 of myocarditis and hypertension

Jewel Holt Vaught, Chicago, Central College of Physicians and Surgeons, Indianapolis, 1903, aged 68, died, October 30, in Williamsfield, Ill.

Joseph David Franklin Dove, St. Joseph Mo., Rush Medical College, Chicago, 1888, aged 76, died, November 10, of coronary occlusion

Hilliard Neil A. McLean, Detroit, Detroit College of Medicine, 1899, aged 67, died, September 18, at his home in Farmington, Mich.

Helen Gyori, New York, Magyar Kiralyi Pazmany Petrus Tudomanyegyetem Orvosi Fakultasa, Budapest, Hungary, 1902, died November 6

Adelbert Beeman Allen ♂ Richmond, Maine, University of Vermont College of Medicine, Burlington, 1904, aged 63, died, October 8

Roy Armstrong Bond, Toronto, Ont. Canada, University of Toronto Faculty of Medicine, 1915, aged 59 died, November 9

DIED WHILE IN MILITARY SERVICE

Vincent Giuliano Maggiore, Brooklyn, University of Virginia Department of Medicine, Charlottesville, 1928, captain in the medical corps of the Army of the United States, attached to Company D, 7th Medical Battalion, Camp San Luis Obispo, California, began active duty Aug. 8, 1942, aged 38, was killed in a railroad accident at Casmalia, Calif., December 5

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of patent medicines, medical devices and cosmetics have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the 'Cease and Desist Orders' of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Besol—This is put out by Besol, Inc., Cleveland, as a treatment for the paroxysms of asthma. In July 1942 that concern signed a stipulation with the Federal Trade Commission in which it agreed to discontinue any advertisements which failed to reveal that its product should not be used by persons suffering from high blood pressure, heart disease, diabetes, thyroid, goiter, lung disorders or skin rash and that the prescribed dose should be diminished or use of the products discontinued if sleeplessness or nervousness should develop. It was provided however that the advertisements need contain only the statement "Caution Use only as directed" if the directions for use in the labeling contain a warning to the same effect.

Chamberlain's Lotion—In August 1942 the Chamberlain Sales Corporation and its President L. H. Chamberlain, Des Moines, Iowa, stipulated with the Federal Trade Commission that they would cease representing that any test made to show that Chamberlain's Lotion flows more readily than other lotions indicates that it is superior to either or that other lotions containing tragacanth gum or other filler are sticky. Chamberlain's Lotion was mentioned in an earlier stipulation signed with the Commission in December 1936 by a Des Moines concern then known as Chamberlain Laboratories in which it agreed to cease representing in advertisements that Chamberlain's Lotion will revitalize the skin and enable it to retain the radiance of youth; that it is a complete beauty treatment containing a blend of thirteen imported oils each of which is noted for a specific skin need; that it will prevent sunburn, windburn and cracked skin in all cases and that it is a complete potent treatment for athlete's foot.

Floting Oil of Castor—This is a permanent wave solution put out by B. E. Sanders, Inc., Tulsa, Oklahoma. In July 1942 that concern stipulated with the Federal Trade Commission that it would cease representing that its product is a new type of permanent wave solution and will nourish the hair or that it contains less ammonia than that found in other solutions used for the same purpose. The Sanders firm further agreed to cease representing that its preparation is sold by means of a special introductory or limited offer and by use of the words "Floting Oil of Castor" that the oil ingredient is composed principally of castor oil.

Hemorrontment—This is put out by a Frank Hill trading as Hill Laboratories, Cartersville, Ill. In July 1942 Hill stipulated with the Federal Trade Commission that he would cease representing that his product is a remedy for the healing or cure of hemorrhoids or that it contains no harmful ingredients or is guaranteed unless the terms of the guaranty are fully set forth. Further, Hill agreed to drop the use of the word "Laboratories" in his trade name and to cease representing in any other way that he owns, operates or controls a laboratory.

Henry Yee Herb Company—Under this trade name one Yee Why, also known as Henry W. Yee of Sacramento, Calif., sold herbs for the treatment of various diseases. In a stipulation that he signed with the Federal Trade Commission in August 1942 he agreed to cease representing by means of advertisements sent through the mail, radio broadcasts or other media that his herbs can be depended on to purify the blood or impart normal healthy tone to the body or that they constitute a competent treatment or effective remedy for nerve symptoms or pains, nervousness, neuritis, rheumatism, liver or kidney disorders, cancer of the bowels, heart trouble, anemia or other ailments.

Kema Tablets and Kema Tea—These are sold by one Harry C. House, trading as Western Natural Foods Company, Seattle. In July 1942 House signed a stipulation with the Federal Trade Commission in which he agreed to discontinue these misrepresentations that either of his products has value as a weight reducer or an accessory or supplemental food or dietary aid or has any significant food value; that either one supplies mineral colloids essential to hydrolysis, saponification, oxidation or elimination of fat; that Kema Tea keeps organs of elimination in proper working order or that either product is harmless. House further stipulated that he would discontinue any advertisements which failed to reveal that his preparations should not be used when abdominal pain, nausea or other symptoms of appendicitis are present or that frequent or continued use of his products may result in dependence on laxatives, provided however that such advertisements need contain only the statement "Caution Use only as directed" if and when the label contains directions which include a warning to the same effect.

Makasar Wonderfult Pomade and Makasar Wonderful Pomade Double Strength—These were represented as having value in treating conditions which cause falling hair by Mack Jenious and Gensie Jenious trading as Makasar Beauty Products Company and Mine Gensie Jenious and Company, Montclair, N. J. In a stipulation that these persons signed with the Federal Trade Commission in August 1942 they agreed to discontinue such misrepresentation.

Minra—This is a product of the Stayner Corporation, San Francisco, whose advertising is handled by an agency in the same city known as Erwin Wasey and Company of the Pacific Coast. In August 1942 this agency signed a stipulation with the Federal Trade Commission agreeing to discontinue any advertising which represented among other things that Minra is a remedy or cure for acidosis, indigestion, influenza, infection, headaches or toxemia that it furnishes the necessary materials to produce sound teeth, bones, muscles or good health or gives protection against mineral deficiencies or that any of the results claimed for the product have been proved by tests made at universities or colleges or by competent trainers or coaches or on college athletes.

Naturene—In July 1942 the Swiss Pine Importing Company, Inc., New York, stipulated with the Federal Trade Commission that it would cease advertising that this hair dye restores the original or natural color of the hair, is harmless and does not stain the scalp. The company further agreed to discontinue any advertisements which failed to reveal that Naturene contains a metallic salt and hence must be used with care. The stipulation provided however that it would be sufficient for the advertisements to state "Caution Use only as directed" if and when the directions for use wherever they appear in the labeling contain a warning to the same effect.

Pelmannism—This system also designated Pelman Institute's Complete Course of Correspondence Instruction in Scientific Mind Training is promoted by the Pelman Institute of America, Inc., New Rochelle, N. Y. In July 1942 that concern stipulated with the Federal Trade Commission that it would cease using the word "Institute" as part of its corporate or trade name or in any other manner so as to imply that its correspondence school is conducted for the promotion of learning such as philosophy, art or science or has equipment and a faculty such as to entitle it to be designated an institute, would discontinue representing that its home study course in mind training, also known as Pelmannism, trains the mind as a physical instructor trains the body, develops character, helps to make friends or opens the way to honor, wealth or happiness, increases energy or enlarges capacities for enjoyment, shows how to banish forgetfulness, brain fog, indecision, self-consciousness or lack of ideas, teaches one how to acquire a keen or infallible memory or a masterful personality and can be depended on to cause students to attain material, social and intellectual success. The concern further agreed to cease representing that Pelmannism is endorsed by the world's leading educators, that it has offices in various foreign cities, that its correspondence school has a staff of trained psychologists or a faculty of instructors or that students receive personal instruction.

Pixacol—This is sold by one Bernard Sincerman trading as Pixacol Company, Cleveland. In September 1942 he signed a stipulation with the Federal Trade Commission in which he agreed to cease representing that his product is a cure for psoriasis. He further agreed to discontinue any advertisements which failed to reveal that Pixacol may irritate the skin particularly if applied with rubbing, that the user should avoid getting it into his eyes or on mucous membranes and that it should in no case be applied to large areas of the body. The stipulation provided however that it would be sufficient for the advertisement to state "Caution Use only as directed" when the directions on the labeling contain a warning to the same effect.

S. C. S. Corn Salve and S. C. S. Athlete's Foot Salve—These products are sold by Anton and Oldrich Sebeck, operating as S. C. S. Chemical Company, Chicago. In September 1942 these persons stipulated with the Federal Trade Commission that they would discontinue the following misrepresentations: that the corn salve is a remedy or cure for corns or will enable one to get rid of them or is a remedy or cure for calluses or warts; that the foot salve will cure athlete's foot or ring worm or effectively treat these conditions unless such claims are limited to cases which are not deep seated or that the foot salve is effective in the treatment of eczema. The Sebecks further stipulated that in the sale of the foot salve or any product of similar composition it would not disseminate any advertisements which fail to reveal that it should not be applied to extensive areas of the body or used continuously for an extended period and that its use should be discontinued if a skin irritation appears and that they would cease using any advertisements of S. C. S. Corn Salve which did not include the warning that it should not be applied to sores, ulcerations, open wounds or any area of the body other than that under treatment. The stipulation provided however that advertisements of either preparation need contain only the statement "Caution Use only as directed" if the directions for use on the labels contain a warning to the same effect.

Sun Ra Vitamin Ointment—In a stipulation signed in July 1942 with the Federal Trade Commission by a John A. Mause and an Arthur S. Ryan doing business as Sun Ra Company, Gloucester, Mass., these persons agreed to cease representing that their product is a remedy, treatment or cure for eczema or is of any value in treating psoriasis, insect bites, abrasions or skin irritations beyond having a limited value in the treatment of bites of nonvenomous insects and in the relief of minor abrasions and skin irritations; that the preparation is healing or contains boric acid or has no harmful ingredient. Mause and Ryan further agreed to cease using the word "Vitamin" as part of the brand name for their product or otherwise representing that it has any merit by reason of any vitamins that it may contain.

Correspondence

TRAUMA AND CORONARY OCCLUSION

To the Editor.—In the October 3 issue of *THE JOURNAL* on page 392, Master took issue with your editorial quotation of my paper (Sigler, F. H. "Trauma of the Heart Due to Nonpenetrating Chest Injuries," *THE JOURNAL*, July 11 1942, p. 835) that trauma can produce coronary occlusion.

It was not my intention in the paper cited to show that trauma may produce merely coronary occlusion although no one has as yet disproved such a possibility. My purpose was to demonstrate that trauma of the heart may be caused by nonpenetrating injuries to the chest and other parts of the body.

If myocardial infarction develops, and that I have definitely demonstrated in those cases in which I claim that it had occurred, it is immaterial whether the infarction was induced through the intermediation of coronary occlusion or by direct injury to the heart muscle. The very recognition of coronary occlusion is by the myocardial infarction it produces. In the absence of demonstrable infarction after an assumed attack of coronary occlusion we must question the correctness of the diagnosis although coronary occlusion might occur without infarction in a small percentage of cases. Myocardial infarction may occur without complete structural coronary occlusion as seen on postmortem examination. In such cases it is due presumably to prolonged coronary spasm during life or to sudden strain thrown on a heart which has a poor coronary blood supply.

We cannot entirely agree with Master's statement that coronary occlusion (coronary thrombosis) is a complete closure of a coronary artery with massive confluent thrombus and through infarction is a rule. The amount of infarction caused by coronary occlusion varies directly with the size of the artery occluded and inversely with the extent of the collateral circulation. Any size and variety of infarction may be observed even in occlusion of the same vessel in different individuals. We also must not mix up the terms coronary occlusion and coronary thrombosis. Whereas the latter invariably implies coronary occlusion the former may represent a closure of a vessel by any other process than thrombosis. For instance capillary hemorrhage in the vessel wall may occur in sufficient degree to occlude the lumen of the vessel as was recently shown by Wartman and by Patterson. Also the rupture of a so-called atheromatous abscess may produce occlusion as suggested by Leary. In such cases intravascular thrombosis may supervene, but the primary process is not thrombosis. Some such process may occur in a vessel in trauma of the heart or as a result of severe strain. However whether or not this occurs is irrelevant as long as we can demonstrate the presence of myocardial infarction or other traumatic changes after an injury.

Patient 4 of my paper which Master selected for criticism was not seen by me until four weeks after the accident. The patient was treated in some hospital, which reported to me that he showed evidence of coronary thrombosis soon after the accident. It is for that reason that I could not present more detail of the early phases of the disease. The subsequent course and electrocardiographic changes together with the history, however, speak for themselves.

It is unfortunate that we have been considering the problem of traumatic injury to the heart from the narrow point of view of the occurrence of coronary thrombosis and not of trauma to the heart as a whole. Pro and con opinions have been rendered in the same case by cardiologists, based on insufficient experience and on improper investigation of the field in the past. The cardiovascular changes in few cases of bodily injuries have been studied soon after an accident, and the profession is simply ignorant of the frequency of occurrence and the extent of traumatic injuries to the heart.

A good start in the proper direction of investigation of this problem has recently been made by Barber (Hugh) "Electrocardiographic Changes Due to Trauma," *Brit Heart J* 4 83 [July] 1942. He found abnormal electrocardiographic changes in 8 out of 33 accident cases in which studies were made within the first few days after an accident.

LOUIS H. SIGLER, M.D., Brooklyn

THE KENNY TREATMENT IN INFANTILE PARALYSIS

To the Editor.—Dr. McCarroll in *THE JOURNAL*, October 17 states that he feels sure the Kenny method of treatment for the disease infantile paralysis would in time take its place among the others offered by the field of physical therapy as having been tried but found wanting.

The application of physical therapy in the past was for symptoms that did not exist and, consequently the results could not have been satisfactory. I am not referring to the pathology of the disease but to the symptomatology.

The symptomatology accepted by Dr. McCarroll, for which physical therapy has had no response—in fact, according to his investigation, has proved damaging—is that previously accepted throughout the world. It may be explained by an extract from *Public Health Bulletin No. 242* presented to me by the National Foundation for Infantile Paralysis on my arrival in the United States of America:

The damaged nerve cells are in the cord inaccessible to any form of treatment their recovery being based on the character and degree of injury they have sustained. At this point appears the importance of the muscle a tissue in no way directly attacked by the virus but rendered useless by its loss of innervation as an automobile with its battery stolen. The muscle undergoes certain degenerative changes the most important of which is its loss of tone or state of tension so that instead of being taut and elastic it is relaxed easily stretched and sagging like a hammock between its points of origin and insertion.

The result of treatment by physical therapy as it is practiced throughout the world is presented by Dr. McCarroll in (1) the *Journal of Bone and Joint Surgery* October 1941, and (2) *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, October 17 and reads:

	Percentage of Normal Recoveries
Group 1 Immobilization 1 to 4 months No physical therapy	9
Group 2 Immobilization 1 to 3 months Physical therapy 3 to 6 months	0
Group 3 Immobilization 4 to 18 months No physical therapy	2
Group 4 Immobilization 3 to 12 months Physical therapy 8 to 24 months	13
Group 5 No treatment	17

It will be seen by this statement that physical therapy, as it is practiced, not only failed to achieve results but prevented recovery in a certain percentage of cases.

The Kenny concept of the symptomatology (which is just the opposite to that already quoted) first appeared in *THE JOURNAL*, June 7 1941. This concept appeared in the report of my work presented by Dr. Wallace Cole professor of orthopedic surgery and Dr. Miland Knapp professor of physical therapy University of Minnesota Medical School and reads:

Miss Kenny has presented ideas which are new to us in the symptomatology and treatment of infantile paralysis. According to this concept the cardinal symptoms of infantile paralysis are to use her terms muscle spasm muscle incoordination and mental alienation. This is opposed to the usual concept where the cardinal symptom is flaccid paralysis without spasm or incoordination. The presence of spasm has been demonstrated in 100 per cent of the acute cases observed in this study.

The results of the treatment given for this concept also appeared in (1) the report mentioned and states that there were 55 per cent recoveries to normal in 326 days, and (2) the records

of the Orthopedic Hospital, New York, presented to the medical observers of the work at the University of Minnesota and myself by Dr Robert Bingham in June 1942, and reads

- I Orthodox Treatment—absolute bed rest with immobilization by means of splints or plaster casts and shells for protection of weak and paralyzed muscles, prevention of and correction of deformities and physical therapy and muscle training
- II Orthodox plus Kenny Treatment—substitution of the Kenny methods on patients who had received the classical treatment at onset of their illness and for some period of time
- III 'Kenny Treatment—for symptoms in the acute stage, bed rest and hot moist fomentations for muscle spasm, passive motion to restore awareness in mental alienation and muscle reeducation for muscle incoordination and recovery of muscle power

The average duration of hospitalization in the three groups

Group I	16 months
Group II	9 months
Group III	6 months

Estimated results of treatment

	Orthodox Treatment 12 Patients	Orthodox Plus Kenny 24 Patients	Kenny Treatment 24 Patients
Patients with residual paralysis (muscle groups fair or less)	10 87%	14 58%	8 33%
Number of braces needed (some patients use several)	19 braces	10 braces	6 braces
Patients needing braces or surgery	6 50%	8 33% (?)	4 16% (?)
Patients with deformities	9 75%	6 25% (?)	2 8% (?)
Functional result			
Excellent	1	6	11
Good	3	8	10
Fair	4	7	3
Poor	4	3	0

The results obtained by physical therapy taught at the University of Minnesota and the City Hospital, Minneapolis, for the true symptoms of this disease speak for themselves and need no comment from me.

The evidence presented in this communication is not my own but supplied by physicians. The slides presented by Dr McCarroll throughout the state of Missouri and elsewhere, presenting certain patients treated at the Gillette State Hospital, were not patients who had received the Kenny treatment.

ELIZABETH KENNY, Minneapolis

PREMEDICAL EDUCATION

To the Editor—The urgency of the need for military physicians has revived discussion concerning the length of time a student must spend in premedical education. A rigid requirement of four years and a degree for entrance in a medical school is unnecessary and unwise. I do not believe that the average medical student who was obliged to spend four years in academic work is superior enough to those who have not to justify the expense in money and years. While it may be desired and even urged for the student who is exceptionally receptive, young and well financed, many students unfortunately have neither the ambition nor the ability to absorb the kind of education they are exposed to, regardless of their financial backing. Nor does the average student need a prolonged classical education to become a good doctor. If a student does not or cannot acquire "culture" during or after his professional education, there is little likelihood that he will obtain it by forced requirements of years, credits or degrees in colleges. Furthermore, baccalaureate degrees in many cases have lost their prestige through mass production, so that they are now often mere tags of educational processing and not the rewards for scholarly attainment for which they were originally intended.

This is not the place to discuss the faults or shortcomings of the organization for primary and secondary education or to offer suggestions for its improvement. Neither is there need to recall how old the average medical student is under the present system before he is able to practice. It would seem that for the majority of students one year or, at most, two years of premedical education as a minimum admission require-

ment should suffice, or perhaps the medical course itself could be expanded to include certain preliminary subjects. As it is, the extra years now demanded for entrance requirement by many medical schools could better be spent in postgraduate work or other medical pursuits for the student who is intellectually receptive, and "culture" will or should accrue with them, with or without extra degrees.

HOBART A. REIMANN, M.D., Philadelphia

THE DOCTOR IN POLITICS

To the Editor—To a second year medical student the comments of Sir Beckwith Whitthouse on the ominous signs appearing in the rising generation of doctors (which you reprinted in the issue of November 7, page 754) were most interesting. Sir Beckwith decried (i) a growing interest in purely materialistic financial success and (ii) a growing interest in assuming active political roles. He disapproved on the grounds that they represented a departure from attention to the doctor's primary avowed concern—the welfare of humanity.

These two interests are not the same. It would rather seem that the more the doctor cares about his job and the more thoroughly he thinks it through, the more ardent a politician he must become. Surely it has been through political activity that some of his most cherished ends have been achieved—compulsory vaccination, regulation of water, milk and food, negative serologic reaction of prospective mates, and so on. But the doctor is also concerned with politics in a broader sense, for example as it affects his patients economically and socially. It is tragic for him to be unable to help one or them because of a far gone malignant growth or because of a constitutional inadequacy; it is almost as tragic to perform a perfect gastrojejunostomy for a patient who has very little to live for once he leaves the hospital.

The scientists of Germany performed the greatest disservice to their country through their aloofness to the political arena and through their clinging to purely technical concerns. It is for the doctor not to disdain political interest but rather to cultivate it because, if politics go badly, his private labors for humanity are pitifully ineffectual, but, if they go well, he is assisted by preventive medicine at its best.

So perhaps Sir Beckwith should cheer up!

NICHOLAS S. GRIMBEL,

BURNS FROM RUBBER SOAKED IN CRESOL

To the Editor—Perhaps attention should be called to an item under "How to Conserve Medical and Surgical Rubber Goods" on page 847 of the November 14 issue of THE JOURNAL. Referring to the care of rubber tubing, the following statement occurs: "Stomach tubes should be rinsed and thoroughly cleansed and then soaked in 5 per cent solution of cresol for one hour." Small tubes for stomach drainage are often left in place for many hours or days. Injury of the mucous membrane from contact of these tubes has been reported. It is pertinent, therefore, to call attention to the absorption of cresol by rubber. 'Burns' of the skin through contact with rubber previously soaked in cresol have been reported (Herwick, R. P., and Treweek, D. N. Burns from Anesthesia Mask Sterilized in Compound Solution of Cresol, THE JOURNAL, Feb. 11, 1933, p. 407).

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Contraceptives Unlawful for a Physician to Prescribe or Advise Use.—A Connecticut statute forbids the use by any person of any drug, medicinal article or instrument for the purpose of preventing conception and declares it unlawful for any one to assist, abet or counsel another to commit such an offense. In *State v. Nelson*, 126 Conn. 412, 11 A. (2d) 880, 115 902 (Sept. 14) 1940, it was held that no exception to this statute could be implied in favor of a physician even when in his opinion the general health of a married woman required the use of contraceptives. In the present case a licensed physician brought an action for a declaratory judgment to determine whether or not he could prescribe the use of contraceptive devices for married women patients: (a) when the patient suffers from high blood pressure so that if pregnancy occurred there would be imminent danger of toxemia of pregnancy which would have a 25 per cent chance of killing her; (b) when the patient suffers from an arrested case of tuberculosis of such a type that pregnancy might reactivate the disease and set back her recovery for several years and might result in her death; and (c) when the patient, though in good health, has been weakened by having had three pregnancies in about twenty-seven months and another pregnancy would probably have a serious effect on her general health and might result in permanent disability. The action was filed in the superior court but was reserved by that court for the advice of the Supreme Court of Errors of Connecticut.

The plaintiff's first claim was that the statute having been originally enacted in 1879 as part of a law against obscenity, had no reference to the medical situation here presented. It was sufficient to point out, said the court, that the statute contained three prohibitions. One was directed against obscene pictures and literature; a second forbade the use of any drug, medicine, article or instrument whatever for the purpose of preventing conception; and a third, the use of such articles for the purpose of causing unlawful abortion. The latter two stamp the statute as having far wider scope than mere general obscenity. To the plaintiff's argument that the legislative history of the statute had no significance, the court pointed out that this claim had been discussed and rejected in the *Nelson* case, in which consideration was given in detail to the repeated and recent refusals of the legislature to inject an exception. Since that decision a so-called medical birth control bill failed of enactment in the 1941 General Assembly. The result of all the attempts to secure a change is that none was made. Year after year there was ample opportunity for the legislature to

create an exception in cases in which life might be in jeopardy if pregnancy occurred. Its refusal impelled the conclusion that not even in such situations as are presented in the present case did the legislature wish to permit exceptions.

The plaintiff contended further that if the statute be construed according to its express language it would violate the state and federal constitutions. But, pointed out the court, the Supreme Court of the United States has held to the contrary in the case of *Commonwealth v. Gardner*, 300 Mass. 372, 15 N. E. (2d) 222, 305 U. S. 559, 59 S. Ct. 90, 1 A. M. A. 112, 576 (Feb. 11) 1939. In that case the Massachusetts court said, in substance, that the terms of the statute were plain, unambiguous and peremptory and contained no exceptions. That the statute was originally enacted in 1879 (as was the Connecticut law), that under the police power the legislature, without any denial of rights under either the state or the federal constitution, might take the view that the use of contraceptives would not only promote sexual immorality but would expose the commonwealth to other grave dangers and that prevention of conception by medical advice and treatment was not unknown in 1879 and might have been the subject of an exception from the general legislative prohibition if the legislature had deemed such an exception consonant with public policy. An attempt was made to have the decision in the *Gardner* case reviewed by the Supreme Court of the United States but the defendant's appeals were summarily dismissed for want of a federal question.

The use of contraceptives, said the court in the present case, is not the only method for preventing conception. There is another method positive and certain in result—abstinence from intercourse. If there is one remedy, reasonable, efficacious and practicable it cannot fairly be said that the failure of the legislature to include another reasonable remedy is so absurd or unreasonable that it must be presumed to have intended the other remedy also. The legislature is the final forum. When the law it enacts comes to the courts an implied limitation on the operation of the statute may be made only in recognition of long existing and generally accepted rights or to avoid consequences so absurd or unreasonable that the legislature must be presumed not to have intended them. Birth control is a highly controversial subject. Social thinking is divergent. It finds frequent expression at legislative hearings. Then the legislature speaks. In the statute involved in this case, the court said, the legislature has intruded on what a large body of intelligent citizens believe are their natural rights and privileges. The answer is that the possession and enjoyment of all rights are subject to such reasonable conditions as may be deemed by the governing authority essential to the safety, health, peace, good order, and morals of the community. In the opinion of the court, the statute prohibits the action proposed to be done by the plaintiff under the circumstances disclosed in his complaint and that statute is constitutional.—*Idelson v. Ullman State's Attorney*, 261 (2d) 552 (Conn. 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints are a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Acidosis with Late Rickets—To their previous studies of 3 children with late rickets and imbalance of acid base metabolism, in 1 of whom the rickets was healed through the regular ingestion of sodium bicarbonate, Boyd and Stearns add a fourth patient with late rickets and chronic acidosis whom they have observed intermittently for three years during which time her rickets and osteoporosis healed and remained so under base therapy. Concurrently, most of her metabolic anomalies were controlled and the electrolyte values were restored toward normal levels.

Vaccine Prophylaxis Against Tularemia—After many trials on human volunteers with tularemia vaccines made by a variety of chemical procedures, the one that best satisfied Foshay and his co workers was a vaccine made by oxidation of virulent strains by nitrous acid. Vaccine was administered to 2,145

susceptible individuals exposed to risk of infection. Selection was random and on a volunteer basis. Also during the entire period of preparing the vaccine all laboratory personnel handling virulent cultures and infected animals were vaccinated. The giving of vaccine to recovered individuals was avoided by agglutination tests or cutaneous tests in those with dubious histories. For vaccination three doses of 0.5 cc each were injected subcutaneously and alternately into the arms on consecutive or alternate days. On annual revaccination applicants were given a trial first injection of 0.25 cc, the second and third doses varied in accordance with the appearance and degree of reactions. If general and local reactions were definite no more vaccine was given that year, but if there was no general reaction but decided local reaction the subsequent doses were 0.25 cc each. If neither general nor undue local reaction occurred the subsequent doses were 0.5 cc each. Data indicate that a useful degree of protection was conferred by annual vaccination. Persons who were not completely protected experienced significant favorable modifications in the course of the disease.

Childhood Infection and Tuberculosis—Israel and DeLien studied the records of 982 children whose supervision at the Henry Phipps Institute began between 1924 and 1932, with the intention of determining the effect of infection in childhood on tuberculosis in early maturity. Clinically manifest tuberculosis developed in 36 after the age of 14. The disease was fatal in 14. The annual morbidity rate was three to four times as great among the Negro (121 per cent) as among the white children of the series. The morbidity among females was considerably higher than among males. The morbidity among the females was largely concentrated in the adolescent years, while among the males it was concentrated in the later years. The mean annual morbidity rate was 0.21 per cent for white males as compared to 0.44 per cent for white females, and 0.54 per cent for Negro males as compared to 1.69 per cent for Negro females. The mean annual morbidity rate was 0.1 per cent in white persons not having household contact after childhood as compared to 2 per cent in white persons having household exposure during adolescence and adult life, the corresponding rates for the Negro group were 0.98 and 3.62 per cent. The morbidity rate in persons who had roentgen evidence of the primary type of tuberculosis was not, in the absence of household contact in adult life, significantly higher than the rate in persons with negative roentgenograms. The rate of 0.33 per cent observed in white persons, relatively few of whom had had preventorium care, was not appreciably higher than the rate calculated from comparable data reported in persons discharged from preventoria. The study shows that in early adult life exogenous infection is of greater importance than endogenous breakdown of lesions acquired in childhood.

Effect of Pneumonectomy on Cardiopulmonary Function—Courmand and Berry present data on various physiologic problems that arose following pneumonectomy on 12 adults from 23 to 64 years of age. The operation was performed on 7

after a diagnosis of carcinoma of the bronchus, on 3 for chronic suppuration of the lung, on 1 because of traumatic fracture of a main bronchus that resulted in stenosis and on 1 for almost complete obstruction of a main bronchus secondary to an endobronchial tuberculosis. The pulmonary volume and subdivisions, the maximal breathing capacity, the ventilation, breathing reserve, respiratory gas exchange and state of the respiratory gases in the arterial blood, under basal conditions, during moderate exercise and during recovery from moderate exercise, and the venous pressure, circulation time and vital capacity before, during and after an infusion of 1500 cc of a saline solution in thirty minutes were determined for 10 patients and compared with normal controls. Two of the 10 patients were again studied after a thoracoplasty had been completed and 2, not studied after pneumonectomy, were studied only after thoracoplasty. The chief difference between patients after pneumonectomy and normal subjects was the reduction in their breathing reserve in various states of activity. This reduction caused by a decrease in maximal breathing capacity was greater in the older patients because of the cumulative effect of abnormal hyperventilation. The decrease in maximal breathing capacity was not proportional to the loss of pulmonary volume and was greatly influenced by the state of distention of the remaining lung. The late effects of pneumonectomy on gas exchange in the lungs, respiratory gases in the arterial blood and the cardiocirculatory function were insignificant. In 2 patients aged 53 and 63 distention of the remaining lung due to a mediastinal shift was detrimental to hemorespiratory gas exchange especially in the older 1, who had pulmonary emphysema. A supplemental thoracoplasty on 4 patients did not further impair the ventilatory function and to some it was of distinct benefit. Overdistention of the remaining lung following pneumonectomy, as far as it impairs the mechanics of the chest bellows and reduces the efficiency of gas exchange is physiologically undesirable.

Thrombophlebitis and Embolism—The disadvantages of heparin are that there is no reliable way to identify individuals susceptible to thrombosis and that it will not dissolve a thrombus, so that when the drug is discontinued a propagating clot may still form at the site of the thrombus or a new thrombus may form. There is no way of knowing when it may be safe to discontinue its use. Fine and his associates believe that the procedure of Homans and of other authors in which the femoral vein was divided as a prophylactic measure against embolism in thrombophlebitis of the lower leg has not acquired the vogue it deserves. Results in the authors' first series so treated agreed with those of Homans: embolism did not occur and the phlebotic process in the leg subsided, in some instances at a remarkable rate. Pain decreased or disappeared in a day or two, and edema frequently began to subside more quickly than might be expected. The result was analogous to that obtained by procaine hydrochloride block of the paravertebral sympathetic trunk and was presumed to be due to the breaking of a reflex arc, producing vasospasm and its undesirable sequelae. Their experience with 20 additional patients among whom division of the femoral vein for the prevention of embolism in all cases of thrombophlebitis of the deep veins in the lower leg was practiced has led to the following conclusions: 1. Division of the common femoral vein will cause early resolution of the thrombophlebotic process in the lower leg. 2. The former practice of dividing the femoral vein, by preference below the entrance of the vena profunda, has been abandoned in favor of division above, because of an occasional instance of embolism from the vena profunda. 3. When thrombophlebitis of the lower leg is present, division of the common femoral vein is preferable to heparinization or paravertebral procaine block as a prophylactic measure against embolism. 4. The occasional individual in whom the process does not remain confined to the deep veins in the lower leg must be reclassified as 1 with iliofemoral thrombophlebitis and treated accordingly. 5. If one infarct should occur in such a patient, regardless of the type of management that has been in effect, division of either the common femoral or iliac vein above the site of, or after extraction of, the clot or thrombus should be performed. 6. Venography is an indispensable aid to the correct management of all types of thrombophlebitis of the lower

extremity. A filling defect in a venogram does not prove thrombophlebitis unless vasospasm has been ruled out. Until an effective method for achieving this becomes available, the venogram should be interpreted in the light of the concomitant clinical picture. The venogram serves a useful purpose in thrombophlebitis of the lower leg of a patient who complains of pain in the legs before or after becoming ambulatory following operation or prolonged illness but who presents no local signs, in iliofemoral thrombophlebitis, in chronic ulcer of the lower leg and in varicose ulcer.

Bone Growth from Water in Ears—Van Gilse observed exostosis in the external auditory canal of cold water swimmers. Fowler and Osmun encountered in three years 25 patients with hyperostosis and 9 with discrete exostosis of the external auditory canal. Changes produced in auditory canals of guinea pigs by cold water were striking not in the external auditory meatus but in the middle ear. There was diffuse production of new bone in the submucosa of the bulla of the middle ear on the experimental side. The new bone formation was more or less proportional to the number of times the cold water was used as a stimulus. There were no changes in the labyrinthine capsule except for slight growth of new bone on the most exposed portion of the promontory. Microscopic evidence was not sufficient to explain the formation of new bone on the basis of infection. In the external canal of the experimental ears, slight fibrosis and hyalinization of the soft tissue and occasionally a small amount of new bone was present. This alteration was never sufficiently striking, as compared with the control side, to be of certain experimental origin. The observation of van Gilse that cold water swimming can often cause discrete exostosis or hyperostosis of the external canal is confirmed.

Journal of Clin Endocrinology, Springfield, Ill

Insulin Allergy—Goldner and Ricketts use the term "allergic" in referring to symptoms due to the antigenic property of insulin as a protein substance, and sensitivity and insensitivity in referring to the response of the body to the specific metabolic function of insulin as a hormone. About 20 per cent of persons within a week to ten days of beginning treatment with insulin have swelling and erythema at the site of injection which persist for thirty minutes to several hours. Itching and induration may be present. Usually these reactions will not interfere with the action of insulin and will disappear without special care after ten days or two weeks. Sometimes changing the brand of insulin may be helpful. In a few patients the reactions increase in severity, extend in size and spread over the body causing generalized urticaria with involvement of the mucous membranes, severe pruritus, articular pain, headaches, elevated temperature and circulatory gastrointestinal symptoms. These reactions do not subside spontaneously but require desensitization or discontinuance of treatment. The observation on generalized insulin allergy in 8 patients encountered by the authors in the metabolism clinic of the Billings Hospital from 1937 to 1941 and the 15 from the literature, indicates that this condition occurs predominantly in middle aged or older patients with moderately severe diabetes. Interrupted treatment with insulin predisposes to allergy. Cutaneous tests are advisable for all patients of whom treatment is resumed and for those with clinical symptoms suggestive of insulin allergy.

Sulfonamide Therapy in Gonococcal Infection—Adair and Hac treated 453 ambulatory women and 80 children for gonorrhea with one of the sulfonamide derivatives. Cures were obtained in 52, 49, 65 and 75 per cent of the patients treated respectively with sulfamidamide, sulfapyridine, sulfathiazole and sulfadiazine. Patients were designated as cured when tests remained negative through two consecutive menstrual periods followed by negative provocative tests. Failures (16, 8, 5 and 3 per cent respectively for the four drugs) occurred in patients from whom evidence of reinfection could not be elicited. Most of them had cultures that remained consistently positive throughout treatment. All the delinquent cases (8, 13, 3 and 7 per cent) were negative for more than a month and were probably cured, but as further observation was not possible they are not considered as cured. Reinfections (34, 30, 27 and 15 per cent) were considered probable in patients who either had spermatozoa in their smears or admitted sexual contact. Women

responded rapidly to sulfonamide therapy and became noncontagious much earlier than with local treatment. Of those cured with sulfathiazole, 97 per cent had negative smears and cultures within four days of treatment, and of the ones treated with sulfadiazine 98 per cent responded within four days. Secondary complications were rare when sulfonamides were administered early. None of the patients discharged as cured required surgical treatment for complications. There was only one drug fast strain of gonococci among the 453 women. Sulfathiazole appears to be the drug of choice for vulvovaginitis in children. Sulfamidamide is contraindicated because it tends to produce drug fast strains.

Gunshot Wounds of Liver—Countryman advocates the following principles in treating gunshot wounds of the liver: rapid and immediate surgery, control of hemorrhage, muscle transplant tamponade of the liver injury, search for additional visceral injuries, prevention of slough and infection of the entering wound, treatment of shock, rest with adequate morphine therapy, sulfonamides, tetanus toxoid and postoperative treatment which includes repeated urinalysis, transfusions, determination of the icterus index and leukocyte counts and drainage to control the infection which is always present. Secondary hemorrhage and sepsis are the most frequent causes of death. Through rapid efficient handling of this serious abdominal emergency and the application of an easily obtained transplant which would obviate gauze packing and its removal, a small percentage of lives may be saved.

- The Trace Mineral Elements in Nutrition J Forman Columbus—p 937

Artificial Fever and Chemotherapy in Treatment of Neurosyphilis—Since 1931 Kendell and his associates have subjected 1,376 patients to artificial fever therapy. Of the 271 patients treated for neurosyphilis the records of 64 were excluded from consideration because of incomplete observation. Of the remaining 207, 52 per cent had remissions and an additional 28 per cent were improved by the treatment. The concurrent use of chemotherapy with artificial fever therapy increases the therapeutic effectiveness of both agencies. Recent developments have demonstrated that equally favorable clinical and serologic results may be obtained with fewer total hours of artificial fever therapy applied during shorter individual sessions at more frequent intervals. This permits the treatment of more patients at less cost.

Renal Complications from Sulfonamide Therapy—Conditions which favor occurrence of renal disease with sulfonamide therapy, according to Monto, are previous renal damage, toxicity of the disease, idiosyncrasy to the drug, the quantity of the drug given in a unit of time, the general condition of the patient and the sulfonamide drug used. The sulfonamides are toxic materials and may act on the kidneys in a manner similar to other renal irritants producing toxic nephritis. A second intrarenal lesion is found in those patients in whom a preexisting nephritis was present and in whom reabsorption of the drug in the convoluted tubules is faulty. This results in an increased

concentration and deposition of the drug in a crystalline form in the tubules. As for extrarenal lesions, anuria and anemia have been reported to result from intravascular hemolysis as produced by sulfanilamide and by plugging of both ureters with calculi of the drug. Several facts cast doubt on the principle that most of the anurias are caused by precipitation of the acetylated drug in the tubules. If anuria were so produced the quantitative analysis of renal tissue would show a much higher renal concentration of the acetylated form of the drug. Anuria due to complete occlusion (plugging) of collecting tubules, from multiple myeloma and from crush syndrome has been previously reported. Treatment of anuria following sulfonamide therapy is chiefly prophylactic and consists of fluid intake, daily determination of the blood level of the drug, daily urinalysis in search of albumin and blood cells and the discontinuance of the drug at the first sign of renal failure. Immediate catheterization of both ureters is indicated when anuria occurs and if the patient has signs and symptoms of renal colic with diminution of renal output. In the event of mechanical blocking the renal pelvis should be irrigated with warm saline solution to dislodge the calculus. If the anuria is not mechanical the usual therapeutic measures are indicated. Stripping the renal capsule has resulted in the resumption of renal function in a few cases.

Sulfonamide Anuria—Kertzer and Campbell report their ninth and tenth cases of sulfonamide anuria, both followed by pyridine therapy. Both patients were cured by ureteral lavage and aspiration at frequent intervals. Concretions reformed in the urinary tract of 1 patient when the catheters were withdrawn prematurely. If anuria reappears, a repeated cystoscopy is indicated. Forcing of fluids expedites recovery. No permanent renal damage was sustained. The authors have had no deaths from sulfonamide anuria. They believe that concretions form in the urinary tract on a mechanical basis. Once in the ureters they are difficult to dislodge. A small urinary output does not effectively cleanse the lower ends of the ureters of crystals. The concretions then form in thrombotic like fashion.

Prognosis of Carbon Monoxide Poisoning—The records of 15 mentally disordered patients who had attempted suicide by illuminating gas or motor exhaust gas were studied by Van Amberg to determine the factors that might indicate or influence the course of the toxic exchanges. One patient survived three serious exposures to illuminating gas; all the others survived one exposure. Illuminating gas was chosen by 11 and motor exhaust gas by 4. Sensorium or neurologic changes were not experienced by 4 patients who were sufficiently exposed to cause acute symptoms but not unconsciousness, nor were changes suffered by the 4 who were unconscious up to thirty minutes. Two patients who were unconscious about one hour had transient neurologic changes, 1 enjoyed an intact sensorium but the other encountered the complication of cerebral arteriosclerosis. The 5 patients who were unconscious from three hours to ten days showed extreme variability in the power of recovery. Apparently a patient poisoned by carbon monoxide is not likely to have serious sequelae if he regains consciousness within one hour after being removed from the toxic atmosphere. There was no important clinical difference between the toxicity of motor exhaust gas and that of illuminating gas.

Cancer in Childhood—Ritvo and his associates point out that according to the census, 153,846 persons died of cancer in the United States during 1939, and 1,103, or 0.7 per cent, of these were less than 15 years of age. The vital statistics of Massachusetts for 1939 further show that the death rate for cancer in childhood was greater than for pertussis, pulmonary tuberculosis, measles, diabetes, cerebrospinal meningitis, syphilis, scarlet fever or typhoid, the only diseases which had higher death rates were "influenza," diseases of the nervous system, appendicitis, diarrhea, the enteric diseases and pneumonia. During the last twenty-five years the number of deaths from cancer in children has increased, while for many diseases common in infancy and childhood there has been a progressive decrease. At the Boston City Hospital from 1915 to 1939 inclusive, 72 children died of malignant neoplasms. Twenty-three were intracranial neoplasms and tumors of the kidney comprised the second largest group. The most common tumors were glioma (medulloblastoma, astrocytoma and mixed gliomas), Wilms's tumor, osteogenic sarcoma, Ewing's sarcoma and miscellaneous soft tissue sarcomas. There were 3 examples of carcinoma of the adult type. Among the earliest instances of cancer were a Wilms tumor at 1 year, a medulloblastoma at 1 and 2 years and a fibrosarcoma at 2 years. The only congenital tumor in the series was a malignant teratoma of the orbital region.

Irradiation of Cancer of Lip—From January 1926 to January 1936, 636 cases of cancer of the lip were irradiated at the State Institute for the Study of Malignant Diseases. According to Schreiner and Christy, cancer of the lip occurred thirty-eight times more frequently in men than in women, and about twenty-nine times as often on the lower as on the upper lip. There were 619 men and 17 women. The upper lip of 22 was involved, 2 of whom were women. The youngest patient was 28 and the oldest 92. The climatic conditions to which farmers, postmen, painters and the like are subjected was an etiologic factor, 201 of the 636 cases fell into this category. The use of tobacco was common, 546 of the men and 7 of the women used it. The oral hygiene of 258 was considered to be bad. In 389 there was a history of cracked or chapped lips or chronic fissure, 197 cases presented definite histories or signs of keratosis. Of 334 patients with primary cancer and no demonstrable metastasis or enlarged lymph nodes, 232 remained well five years or longer, 69 died from intercurrent disease with the local lesion healed, 18 were lost from observation with the local lesion healed and 15 died of uncontrollable metastasis. The absolute cure rate for the group is 69.5 per cent. Of 192 patients with primary cancer and palpable, movable lymph nodes (and probable metastasis in some) 131 remained well five years or longer, 19 died of intercurrent disease with the local lesion healed, 19 were lost from observation with the local lesion healed and 23 died from the disease. The absolute cure rate for the group is 68.2 per cent. Of 110 patients with primary

cancer and definite metastasis, 12 were well five years or longer, 6 were lost from observation with unascertained results, 1 died from intercurrent disease with the primary lesion healed and the metastatic nodes sclerosed and 91 died from metastasis. The absolute cure rate for this group is 10.9 per cent. The absolute cure rate for the total series is 58.9 per cent. If the patients who died of intercurrent disease with a lesion healed and those who were lost from observation with the lesion healed less than five years are eliminated, the cure rate is 74.4 per cent.

Geographic Pathology of St. Louis Encephalitis.—Casey describes the methodology of the original study in the St. Louis area of the epidemic of St. Louis encephalitis in 1933 and 1937 and offers evidence that the disease was not spread along the traveled highways, boulevards, interstate railways or navigable streams but along small streams which carried sewage and in areas characterized by weeds, garbage and tin can dumps. The encephalitis was significantly scarce in both epidemics in areas not characterized by weeds, open sewage and ponds. Using an adequate control series and biometric methods no foci were found along the most traveled highways in St. Louis County, along the principal boulevards in St. Louis or along the interstate railroads, and also there was no relation of the disease to congested housing. The disease occurred in the same districts in 1933 and in 1937. Its distribution was different from that of measles. The possibility of a mosquito vector was considered. During both epidemics it was a hot dry year, when evaporation was rapid and sewage concentration was unusual. Something existed along these streams in the weed and tin can areas which started the disease in the same places in two different epidemics and which remained there throughout both epidemics. Such a distribution is for Culex mosquitoes and not, so far as is known, for ticks.

Bronchial Asthma, Sighing Dyspnea and Cardiac Asthma.—The same prominent signs and symptoms may be produced by conditions other than bronchial asthma. Sighing dyspnea and cardiac asthma, the one without wheezing the other with wheezing, Brownian points out, are sometimes confused with bronchial asthma. The syndrome of sighing dyspnea consists of deep sighing respirations which are greatly increased in depth without much alteration in the respiratory rate. The shoulders are elevated with each inspiration and the accessory respiratory muscles act as in an asthmatic attack. The face shows anxiety and distress, and the patient often puts one or both hands to the thorax. It is not uncommon for the patient to run outdoors to get sufficient air. If the attack is long and severe, tetany may occur from hyperventilation. A correct history is the only means of differentiating such an attack from bronchial asthma. The patient should be questioned in detail concerning wheezing, and during the course of taking

the history the patient will often take a deep sighing inspiration. This should give one a clue, but if it does not the stereotyped phrases "I just can't get a deep breath," "I just breathe below this," "I just can't get a satisfying breath," "something prevents air from going to the bottom of my lungs" or "something seems to press on my chest" that the patient uses should suggest the diagnosis. After a patient has given such a lead it is usually a simple matter to determine definitely that he does not have bronchial asthma. Sighing dyspnea is a functional disorder; it may coexist with organic disease, but its underlying cause is always a nervous disorder requiring treatment. Cardiac asthma results from left ventricular failure, but not all persons with left ventricular failure have cardiac asthma. Swineford has reached the conclusion that the cardiac failure has thrown the patient out of allergic balance. This affords an explanation of why some patients with left ventricular failure have asthmatic symptoms whereas others do not. Even though it is assumed that cardiac asthma is nothing more than heart failure in an allergic individual it is still necessary to know that cardiac failure is the underlying cause. Epinephrine is almost a specific for bronchial asthma but may be detrimental to the patient with cardiac asthma. Morphine is almost a specific for cardiac asthma but may be harmful in bronchial asthma. When ordinary means of differential diagnosis fail, circulation time tests are invaluable. The only two tests essential are relatively simple, they are the "arm to lung time" and the "arm to tongue time."

Liquid Petrolatum and Saline Laxatives.—Thiele presents evidence that liquid petrolatum and saline laxatives bear a direct relationship to the incidence of acute anorectal infections. When liquid petrolatum or saline laxatives are taken the passage of the resultant stool is impossible without an oily or watery suspension of bacteria existing under pressure at the mouths of the anal crypts. The suspension is therefore forced into the anal crypts and possibly also into their tributary ducts. Whether or not an acute cryptitis ensues depends on whether the crypts have been previously traumatized, whether or not upper respiratory or enteric infection coexists, the bacteria of which will contaminate the stool, and whether the anal membrane and crypts were irritated by chemical substances contained in the laxative stool, giving the intestinal enzymes insufficient time to accomplish normal intestinal digestion. Once the anal crypt is infected, the infection spreads distally, the anal membrane loses its normal elasticity, fissure results and its subsequent ulceration produces an anal ulcer. Of 160 patients with anal ulcer, the so-called ulcerated anal fissure, for whom accurate records were had 67 had taken liquid petrolatum when they consulted the author. Fifty-eight of these had taken the liquid petrolatum either habitually or in large doses for acute dyschezia, immediately preceding the onset of anal symptoms. Only 9 of the 67 gave a history of having begun its use after the onset of acute symptoms of anal fissure or ulcer. Thirty-three additional patients had taken other laxatives, either habitually or immediately preceding the onset of anal symptoms. The question of whether liquid petrolatum or saline laxatives bear any causal relationship to anal infections was studied in a controlled group of obstetric patients who were instructed to use one of the gum laxatives (instead of the liquid petrolatum or saline ones) without cascara, have a smooth diet in the latter half of pregnancy and drink from twelve to fifteen glasses of water daily unless otherwise contraindicated. Since adopting these simple measures, only 6 of 350 mothers delivered had any rectal complaint or any anorectal disease. Furthermore, the proctitis of these 6 was attributed to improper mixing of the ether and liquid petrolatum for rectal anesthesia. In contrast to this experience, 5 per cent of 1,275 obstetric patients at the obstetric clinic at the University of Kansas School of Medicine, where 1 tablespoon twice a day of plain liquid petrolatum is prescribed routinely for all patients who need a laxative, had anorectal disease. The study raises the question as to whether abnormal bleeding from hemorrhoids or other anorectal lesions may be due to the habitual use of liquid petrolatum by some patients. That liquid petrolatum delays the healing of anorectal wounds is well known. Its administration reduces the blood prothrombin level and may account for some abnormal hemorrhage.

Plasma Therapy in Severe Burns—The general treatment of burns attempts to bring the patient past four serious chromologic stages of a burn: primary shock, secondary shock, toxemia and infection. The progressive development of these stages requires that treatment be instituted rapidly, carried out continuously and followed meticulously for as long a time as necessary. Harkins and his associates state that plasma administration is the best form of treatment for primary and secondary shock due to hemoconcentration from loss of plasma into the tissues. Administration of plasma should be quantitatively adjusted to fit the patient. For calculating the necessary dose of plasma when no laboratory facilities are available, the first aid formula should be utilized, that is 50 cc of plasma for each per cent of the body surface (as calculated by the Berkow method) involved by a deep (blistering) burn. There are three methods of calculating hemoconcentration. The formulas of Black and of Elkinton are accurate, but the authors believe that the Harkins formula is therapeutically just as reliable and is much simpler. This method is as follows: The amount of plasma needed can be roughly calculated for an average size adult as being 100 cc of plasma for every point the hematocrit exceeds the normal of 45 as long as the plasma proteins are above 6 Gm per hundred cubic centimeters. When the plasma proteins are below this level an additional 25 per cent of the calculated amount of plasma should be added for every gram the protein is below 6 Gm. Preventive measures against toxemia and sepsis should be carried out along with shock therapy. Toxemia is apt to occur during the second to the fourth day after a burn. Jaundice, increase in the icteric index, decrease in the urinary output, stupor and a demonstrable decrease in hepatic function are prodromal signs. Adequate dextrose and sufficient sodium chloride to maintain equilibrium are indicated. The reasonable use of these crystalloid solutions and adrenal cortex extract to prevent burn toxemia conforms with the control of burn shock. Sepsis is largely preventable by careful local therapy and adequate chemotherapy.

Residual Lesions of Ulcerative Gastritis—Judd evaluates the significance of changes in the gastric mucosa which take place over many years as related to the development of gastric carcinoma. The material examined consisted of 200 carcinomas of the stomach removed at operation and/or necropsy at the Mayo Clinic between 1926 and 1938. For control 78 average stomachs, which were obtained at routine postmortem examination of patients without gastric carcinoma, were examined. For convenience the residual lesions were placed in seven

separate columns: accumulation of lymphocytes, irregularity of the muscularis mucosae, thickening of the muscularis mucosae, fibrosis of the muscularis mucosae, atrophy of the chief and parietal cells, hyperplasia of the mucous cells and disorganization of the mucosal glandular elements. Of the 200 carcinomas not 1 could be placed entirely outside the columns of classification. The control group contained 5 completely free instances. When the final tabulations of the grades of change were examined, certain of the "residual lesions" could not in themselves be regarded as of prime significance in the development of the carcinoma. The most common change in all specimens, whether cancer or control was the accumulation of lymphocytes in the mucosa, either in so called follicles or in diffusely scattered array. The evidence obtained by tabulation of the grade of change in the five residual lesions considered of secondary importance in the pathogenesis of carcinoma was found to be invaluable in the study of the chronicity of the disease. This left for serious primary consideration only two of the residual lesions: atrophy of the chief and parietal cells and hyperplasia of the mucous cells. Atrophy of the specialized epithelial cells was a frequent and consistent observation in the cancer group, in sections made directly through the tumor, 98.5 per cent, and in those cut 10 cm from the edge of the cancer, 91.5 per cent. Hyperplasia of the mucous cells in these two groups was only slightly less frequent, 89.5 and 83.5 per cent respectively. In the control group atrophy was present in 57.6 per cent and hyperplasia in 37 per cent. The consistently lower incidence and decidedly less prominent degree of hyperplasia in the control group lend support to the conclusion that hyperplasia (regenerative activity) is a highly important factor in the pathogenesis of gastric carcinoma. Gastric analysis was recorded for 124 of the 200 patients with carcinoma and 96 of these had no free acid. The neoplasm of 20 of the 200 was suspected clinically of originating as a gastric ulcer. If these 'former ulcer' cases could be disregarded, it would seem that an excellent clinical indicator of the ability of the stomach itself to ward off carcinoma would be the presence of a normal amount of free hydrochloric acid. Hurst expressed much in a few words when he said that carcinoma does not develop in a healthy stomach.

Surgical Treatment of Bilateral Bronchiectasis—Blades and Graham performed total pneumonectomy for bronchiectasis on 4 children less than 8 years of age. All recovered. The exact precedents for bilateral extirpation of pulmonary tissue are not yet established but the principal considerations are the age and general condition of the patient, the amount of tissue involved, the degree of involvement and the severity of symptoms. It is the authors' opinion that an operation is rarely justified for patients past middle age with bilateral disease. Cardiovascular disease and other serious conditions preclude lobectomy. The amount of tissue that may be extirpated safely is influenced by a consideration of vital capacity, age and other individual factors. Their experience with 16 other cases of bilateral bronchiectasis, in 4 of which all the tissue but the two upper lobes was removed, has convinced them that in young subjects two pulmonary lobes furnish adequate respiratory exchange for ordinary physical activities. The decision for bilateral lobectomy will therefore depend somewhat on the amount of sputum raised and the inconvenience and disability, that is, the severity of symptoms, that the total sputum causes the patient. For older patients with bilateral disease and mild symptoms, postural drainage, supplemented in some by bronchoscopic aspiration, should be given a fair trial before lobectomy is undertaken. There were four deaths following the twenty lobectomies for bilateral bronchiectasis. Two deaths had no connection (one from tuberculous pneumonia and one from staphylococcal septicemia) with the bilateral distribution of the disease. The chief danger from bilateral lobectomy is suffocation during the operation or from early opening of the bronchus. The upright position for lobectomy minimizes the danger of suffocation, relieves the necessity of rapid operating and allows time for an adequate closure of the bronchus. The oldest patient in the group operated on was 44, lobectomy was performed because, in addition to raising foul sputum, he was completely incapacitated by an intractable cough caused by a partial stenosis of the right lower lobe bronchus. From the patient's standpoint the result of unilateral lobectomy was entirely satisfactory.

Immunization Against Typhoid and Paratyphoid—Clinie compared the Vi antibody of full functional efficiency produced by ordinary alcohol preserved vaccine in nurses and civilian defense workers. Of 106 persons inoculated 44 were given ordinary T A B C vaccine and 62 alcohol T A B C vaccine. The vaccines were given subcutaneously into the arm, at the insertion of the deltoid. There was comparatively little difference from the two vaccines in regard to O agglutinin response. Vi agglutinins were found in 14.4 per cent of the alcohol-vaccine cases, but none appeared in the heat killed phenolized vaccine cases. There was no significant difference in the frequency of local reactions but there were definitely less general reactions in the alcohol vaccine cases.

Dystocia Dystrophia Syndrome—Williams reports 62 cases of dystocia dystrophia encountered in eight years at five maternity hospitals. The incidence is difficult to judge, as only the more striking cases are likely to attract attention. The average age was 28. Details about the previous history were deficient, but a high incidence of menstrual irregularity and sterility was reported. Only 1 of the patients had had a previous full time pregnancy, and it ended in a cesarean section, 4 had had five miscarriages and 8 are known to have had a

subsequent pregnancy, only 3 of whom had a normal delivery. The clinical condition was a contracted pelvis in 15, a funnel pelvis in 10 and a flat pelvis in 1. Toxemia occurred in 36, there was a trace of albumin in 7, increasing edema occurred during labor in 3, edema of the vulva was often prominent and eclampsia occurred in 7. Strong pains at the end of the first and during the second stage in these patients in whom disproportion and malposition are common are probably responsible for precipitating eclamptic fits by raising the blood pressure in an already preeclamptic patient. In 51 the time of the onset of labor was known and in 1 it commenced eight days prematurely, in 3 on the expected date and in 47 on an average of seventeen days after the expected date. The average length of the first and second stages of labor in the 46 in whom it was known was more than fifty hours. Forceps was applied in 48, lower segment cesarean section was performed in 8, a breech presentation occurred in 1, cleidotomy was done in 3 and a destructive operation was performed in 2. The method of delivery gives but little idea of the difficulty of carrying it out on these patients. Usually a high transversely arrested head, the so called persistent occipitoposterior, was to be dealt with. Delivery without episiotomy or extensive laceration and trauma was impossible. The third stage of labor was infrequently complicated. The morbidity in 38 with complicated deliveries was usually due to infection of pelvic origin or of the wound from cesarean section. There were 2 instances of septicemia, 3 of paralytic ileus, 1 of volvulus of the pelvic colon, 1 of puerperal mania, 1 of mania, 1 of massive collapse of the lungs, 2 of phlebitis and 3 of mastitis. Forty-three of the 62 babies were male and 19 female. 21 were stillborn and 4 died. Examination of 17 of the stillbirths showed tentorial tears in 9, maceration in 5 and spina bifida in 1. Of the four neonatal deaths, one was due to a staphylococcal infection, in 1 a ventricular hemorrhage was found and of the 2 in whom postmortem examination was not carried out 1 is described as having had "convulsions." Of the babies that survived, many showed a large caput succedaneum and considerable molding. Asphyxia at birth and signs of cerebral irritation in the first few days were common. One had a fractured clavicle and 1 Erb's paralysis. There was only one maternal death. The enormous risks to a fetus of vaginal delivery in these pregnancies should incline one toward cesarean section. If the pregnancy is extremely prolonged, cesarean section should be carried out before labor starts. When cesarean section is judged unnecessary or unsuitable, early vaginal delivery has fewer risks for the fetus in suitable surroundings and in skilled hands. Once the fetus is dead, craniotomy should be carried out.

Gas Gangrene Bacilli in Human and Animal Organism—Lippelt points out that infections with diphtheria, tetanus and gas gangrene bacilli are unique in that the clinical picture is determined not so much by the organisms as by their toxins. The opinion still prevails that the causal organisms develop almost exclusively at the site of their first localization and that they send their toxin into the organism but without the tendency to invade the blood stream and the internal organs. Opinions regarding the pathogenesis of diphtheria have undergone a change. It has been suggested that the causal organism first enters the blood stream and is then eliminated secondarily by the tonsils. It has been found that diphtheria is not a sepsis that it produces no metastases and that it is rather a bacteremia. The problems of tetanus bacilli are much more difficult. The first world war did not solve them. Twenty years later Mayer and Graetz were able to show that tetanus infection is a bacteremia. Mayer rejects the theory that agonal or postmortem invasion is responsible for the presence of tetanus bacilli in the heart blood and in the internal organs. He demonstrated the intra vitam invasion of the blood stream with tetanus bacilli. The problem of gas gangrene was investigated during the positional war at the Maginot line during 1939 and 1940. The investigators originally believed that gas gangrene bacilli develop locally in the wound and that toxins enter the body only from there. Systematic studies revealed that the organisms are found not only in the wound itself but removed far from it in apparently normal tissues in the internal organs and in the blood stream. In 1 case they were detected on the amputation stump immediately after the operation the amputation having been performed far away from the wound in the healthy part of the extremity. The general condition of this patient was satisfactory. In another case, in which amputation was performed because the wound had completely destroyed the circulation of the lower extremity, the bacteriologic and microscopic examination of the amputated extremity revealed the presence of a severe gas gangrene infection. There were no general symptoms to correspond to the severity of the infection, because of the interrupted circulation between the body and the infected leg. Observations on amputated extremities and necropsy material supported the assumption that the bacilli of the gas gangrene group are disseminated over the entire body by way of the blood stream. Rabbits were used to test the pathogenicity of the freshly cultured gas gangrene bacilli. At the same time observations could be made on the time that elapses between the infection and the appearance of the bacteremia and about the regularity of the positive bacteriologic test in the circulating blood and in the internal organs. The results indicate that gas gangrene is not a sepsis in Schottmüller's sense because there are no metastases. Observations in cases of gas gangrene with positive blood cultures convinced the author that even extensive surgical interventions had little effect. Likewise attempts at energetic serum therapy with the available serums seem to be ineffective. Omission of these measures, nevertheless, must be regarded as an error. In toxigenic infections (diphtheria, tetanus and gas gangrene) emphasis must be placed on early and energetic prophylaxis.

Dysentery in Camps—Dotzer and Schuller report an epidemic of dysentery in a camp. Several mild cases had appeared from the middle of October until the end of December. On December 28 an epidemic suddenly flared up. Until the evening of this day 480 men, or 20 per cent of the inmates, had severe dysentery with temperature up to 105.8 F, chills and severe diarrhea. At the end of the week 30 per cent of the inmates

were ill. The source of infection was probably a potato salad that had been prepared by a cook who was suffering from mild diarrhea. It was impossible to examine the potato salad bacteriologically, but the examination of the cook disclosed that he was a carrier of dysentery bacilli. The mortality of the dysentery was slight, amounting to 3 per thousand. The incubation period was three days in the fulminating cases and four to six days in others. The average duration was from two to three weeks. At the end of the second week many of the patients had edema of the ankles and of the face resembling hunger edema. Neuritic disturbances, chilliness, formication, drawing and piercing pains, and muscular weakness were frequent. Dehydration was mild or moderate. Patients with high fever frequently presented labial herpes. There were also conjunctivitis, stomatitis, gingivitis, burning of the bladder and urge to urinate, without pathologic findings in the urine, and swelling of the inguinal lymph nodes of the left side. After the acute symptoms had subsided there were frequently mild gastritis, dull pain in the epigastrium and subcostus. Bacteriologic studies disclosed dysentery bacilli of the Flexner group. The intestinal smear was twice as exact in demonstrating dysentery bacilli as the simple fecal smear. The bacteriologic demonstration of bacilli during the first three days is comparatively simple. Later it becomes difficult. Quarantine was instituted at once in order to prevent the spreading of the dysentery beyond the camp. Feces was disinfected with chlorinated lime and saponated solution of cresol. All sewage was subjected to chlorination. The kitchen personnel had been examined at the onset and 2 bacillus carriers were excluded. The food was sent from the kitchen in closed containers. Soiled dishes were disinfected with saponated solution of cresol. With the strict enforcement of hygienic measures the epidemic was brought under control in six weeks. At the time the quarantine was lifted 8 bacillus carriers still remained in isolation but in the course of two weeks they had been rendered bacillus free. The most important therapeutic measures were bed rest and diet. On the first day a purge and fasting were usually prescribed. From the second day until the subsidence of the acute symptoms the patients were given first gruels and later pureed foods, the normal diet was gradually resumed. Circulatory remedies were of little effect. Intravenous injection of sodium chloride solution proved helpful, as did high enemas. Rivanol, acriflavine, hydrochloride and a 2.5 per cent soap solution. Rivanol proved effective in bacillus carriers. Resistance influenced by an adequate vitamin content of the food is of great importance in the favorable outcome.

Blood Group Determination from Dried Serum Drops—Wagner points out that for mass examinations approved test serums are sometimes difficult to obtain. He decided to try dried test serum. After the necessary preliminary testing the serum is dropped on white card paper and spread to the size of a small coin. One drop each of test serums A, B and O are placed at distances of about 30 mm from center to center. After the drops have been carefully dried they are ready for use. Although the length of preservability is not definitely known, it is probably at least two months. Simple drying at 37 C of 0.05 cc of undiluted serum yields a product that will produce noticeable reactions even in serums with moderate power of agglutination. The following procedure is employed in the determination of the blood group: 1. A large drop of isotonic solution of sodium chloride is placed with a pipet on each of the dried drops of serum and is left to stand for one minute. 2. Into each drop of the sodium chloride solution there is then placed a small drop of the blood to be tested. It is stirred at the same time at which the sodium chloride solution is spread over the dried serum drop. The blood is taken up with the three corners of a slide. A dilution of 1:5 is aimed at. 3. Good mixing is obtained by a mild movement of the card. 4. The result (agglutination) should be read not before five minutes have elapsed. This dried drop test is a handy form of blood group determination. The card method has the special advantage that the test results can be preserved on the card after drying of the blood serum mixture. The blood drops can be protected against damage by covering them with thin collodion. The card can be kept.

Book Notices

Röntgen Treatment of Infections By James I. Kelly M.D. F.A.C.R. Professor and Director of the Department of Radiology, Creighton University School of Medicine, Omaha. With the collaboration of D. Arnold Dowell M.D. Assistant Professor of Radiology, Creighton University School of Medicine. Cloth. Price \$6. 1 p. 132 with 122 illustrations. Chicago: Year Book Publishers Inc. 1912.

While the employment of roentgen irradiation in the therapy of skin and neoplastic diseases has been adequately covered, no textbook is available on the roentgen treatment of the infections. Although roentgen therapy should occupy a prominent place in the treatment of certain types of infections the definite beneficial and, at times, remarkable results are not generally appreciated. The importance of accurate technique in the treatment of these diseases is too frequently overlooked, and this method of therapy is judged by the results obtained following the careless administration of an unknown or improper dose. The appearance of this volume fills a definite place in the literature of roentgen therapy and it is especially fitting and proper that it is presented by the authors, who have been pioneers and who have contributed so much to the subject. The names of Drs. Kelly and Dowell have been associated with the roentgen therapy of gas bacillus infection for a number of years and a large portion of the book is devoted to this important subject.

This volume is divided into five parts. Part I on x-ray physics and fundamentals is concerned with the dosage factors which are so important in the efficient administration of therapy in these conditions. The intrinsic and extrinsic factors affecting the tissue dose are carefully considered.

In part II the early and present uses of roentgen therapy are discussed. The chapter on the clinical features of roentgen therapy of infections is of considerable value. The description of mobile apparatus and the military use of the x-rays are timely subjects and should serve to limit casualties and deformities.

Part III is devoted to gas bacillus infection and is the outstanding portion of the book. The history, diagnosis, mortality and the surgical and roentgen therapy of gas bacillus infection are discussed. Comparisons are made of the results obtained in animal experiments and in human cases following surgery, serums, sulfanilamide and roentgen irradiation and in various combinations for prophylaxis and therapy. The authors conclude that x-rays alone offer the ideal and most effective means of treatment. Serum is nonessential, amputation and debridement during the acute phase are detrimental. Sulfanilamide and its early derivatives are also highly detrimental. Uniformly consistent results have not always been obtained in clinical cases and animal experiments. Case reports discussed in sufficient detail are employed throughout to illustrate the authors' statements. The importance of individualizing each case treated by x-rays is emphasized.

Various types of abdominal infections, such as peritonitis, are discussed in part IV. As in previous sections, case reports with reproductions of roentgenograms and clinical records are included. Part V includes a miscellaneous group of infections such as parotitis, mastoiditis and pneumonias.

Part VI considers the contraindications to the use of x-rays and contains a brief review of the literature. The authors conclude that the results following x-rays alone are always better than those obtained by the use of sulfanilamide and roentgen therapy. It was noted that the usual good results following x-rays were absent if sulfanilamide was being administered to the patient. The review of the literature and the list of contributors in the last section offer additional evidence of the authors' conclusions in the foregoing sections.

In general, the illustrations are good and the text is clear and concise. This volume should prove of inestimable value to the industrial and military surgeon and radiologist who see or expect to see cases of gas bacillus infection. Since every physician, regardless of specialty, is concerned with infections, this presentation of experimental, clinical and bibliographic evidence of the value and technique of an effective agent in a large group of crippling and fatal diseases should merit universal consideration. It is a necessity to any physician who attempts the roentgen treatment of infections.

The Clinical Application of the Rorschach Test By Ruth Bochner M.A. and Florence Halpern M.A. Psychologist, Bellevue Psychiatric Hospital, New York. Introduction by Karl M. Bowman M.D. Professor of Psychiatry, University of California Medical School, San Francisco. Cloth. Price \$3. 1 p. 216. New York: Grune & Stratton, 1942.

The avowed purpose of this book, as stated in the preface, is to make the Rorschach test "available to all psychologists and psychiatrists." It is therefore warrantable to evaluate it in terms of the degree to which it accomplishes this rather ambitious aim. Perhaps, however, we should question the possibility or indeed, the desirability of attempting to put this tool in the hands of any total group, whether composed of physicians or psychologists. This is not at all to concede, as surprisingly enough the authors seem to, that the Rorschach has been a cult which only the initiated could serve but merely to recognize it as a technique fully as complicated as the reading of x-ray plates by the roentgenologist and therefore properly the function of the specialist.

But, laying this question aside, how well does the book succeed in giving to any hitherto unenlightened person a working knowledge of the Rorschach test? Unfortunately it is not comprehensive enough or sufficiently precise for the beginning student and it is much too cluttered up with detail, too lacking in its presentation of underlying Rorschach philosophy, for the general reader. Not only for historical perspective but because it remains the single great classic in a rapidly growing literature, the student should begin with the *Psychodiagnostik* itself, now happily translated into English. This, followed with Oberholzer's article of twenty years ago in the *Journal of Nervous and Mental Disease*, will establish his firm foundation. Then if he keeps abreast of current material in the psychologic journals and the Rorschach exchange he will see both the many extensions in the use of the test and the new concepts which are being incorporated. Undoubtedly the best exposition of the subtleties and refinements of scoring which are used by members of the Rorschach Institute is embodied in another new book, *The Rorschach Technique*, by Klopfer and Kelley. The present book, then, like Beck's, which came out in 1937, is mainly useful in rounding out the picture with supplementary case material for those already familiar with Rorschach practice.

What is still lacking and what the psychologist called on to present and defend Rorschach personality studies and diagnostic impressions longs for is a new Rorschach classic, a small book like Hart's on insanity. Such a book, stripped of the details that obscure the forest should present the philosophy of personality organization on which Rorschach theory is based and which constitutes its unique contribution. This is what should be "available" to all psychologists and psychiatrists but, unhappily, it is yet unwritten.

The Mentally Ill and Public Provision for Their Care in Illinois By Stuart K. Jaffary, Director, School of Social Work, University of Toronto. The University of Chicago Social Service Monographs, Paper Price \$1.25. Pp. 214. Chicago: University of Chicago Press, 1942.

In the first chapter of this monograph the author summarizes the organization existing in the state of Illinois for the care of the mentally ill prior to 1917. The second chapter discusses the department of public welfare. In the third and fourth chapters the state hospitals and their personnel are studied. The fifth chapter takes up admissions, paroles and discharges. The sixth chapter is an analysis of the development of social service in state hospitals. The seventh chapter takes up education, research and prevention. In the eighth and ninth chapters, part 2, the facilities in the counties are discussed in relation to early examination, diagnosis, treatment and the commitment process. The tenth chapter considers the patient's return to his community. The eleventh chapter elaborates on the facilities in Cook County, Ill. There is an excellent detailed group of conclusions. The author feels, and justifiably so, that "the administration of the public services for the mentally ill in Illinois has been lacking in professional viewpoint and backward in leadership." The drafting of professional men from the medical schools in some instances and of professional men not connected with medical schools in other instances has proved to be full of gross shortcomings. These professional men lack leadership and because of this have permitted a continuation of a narrow policy of institutionalization in many of the hospitals. The author feels that the remedy lies in the

development of a sound professional point of view and direction, a workable department and leadership. With this the reviewer agrees. There is a good index and bibliography. This book is recommended to all the officials of the state of Illinois who are in any way connected with the direction and use of the state hospitals. There are myriads of tangible classified facts.

A Manual of Roentgen Diagnosis. By Kenneth S. Davis, M.S., M.D., Professor of Radiology, College of Medical Evangelists, Los Angeles. Second edition. Cloth. Price \$3.50. Pp. 160 with 279 illustrations. San Francisco: J. W. Stacey, Inc. 1941.

The expansion in teaching of roentgen diagnosis to undergraduates is producing a number of textbooks the use of which permits the limited hours to be available for demonstration purposes. Dr. Davis's book is a compilation of his own lecture notes written in modified outline form, comprehensively and clearly presented. It is produced in lithotype and is small but generously illustrated. Obviously the scope is limited to the rudiments of roentgen diagnosis. Its intent is to give the undergraduate student a brief survey of the field, and in this effort success is achieved.

In an attempt to cover a subject within stringent limitations of space, the problem of selection of material looms large. The fact that approximately half of the book is devoted to diseases of the skeletal system reflects an unfortunate lag in the minds of many teachers who have not fully accepted the truly enormous expansion of roentgen diagnosis in the field of visceral lesions.

There are a few statements which are open to criticism. The distinction between a "fleck" and a "niche" in the diagnosis of duodenal ulcer may well be questioned. Likewise the categorical assertion that carcinoma "arising in an ulcer" is different from ulcerating carcinoma is unjustified. A more serious criticism is the failure to mention roentgenkymography and body section roentgenography or to detail bronchography. Not that the undergraduate need concern himself at length with these details of roentgen examination but he should know what they are and their usefulness. Likewise, insufficient stress is given to the important question of the relative emphasis to be given roentgen examination in the weighing of the diagnostic problem.

The illustrations comprise drawings and reproductions of originals. They vary greatly in quality but, generally speaking, exhibit the lesions which they are intended to demonstrate. The author has wisely reproduced the roentgenograms in the negative and the drawings have been photographed to maintain consistent densities throughout.

This is a satisfactory brief outline and should be useful as a teaching aid.

Preventive Medicine in Modern Practice. Edited under the Auspices of the Committee on Public Health Relations of the New York Academy of Medicine by James Alexander Miller, Chairman, George Baehr, Former Chairman, and E. H. L. Corwin, Executive Secretary. Being the Third edition, completely rewritten of Outline of Preventive Medicine. Cloth. Price \$10. Pp. 351 with 22 illustrations. New York & London: Paul B. Hoeber, Inc. 1942.

The New York Academy of Medicine has taken an active interest in preventive medicine and public health for nearly a hundred years. As a result, its Committee on Public Health Relations has developed a quiet but powerful influence for good in New York City and, indirectly, throughout the United States. This committee has published a large, handsome volume. The book is the outgrowth of a previous publication under the auspices of the academy, "Outline of Preventive Medicine." The present edition consists of forty-nine chapters, with an excellent index. Each chapter is written by a different author. The editors first laid out the plan of the book and then requested each author to write on the special field in preventive medicine in which he is an authority. Most of the authors are members of the New York Academy of Medicine, but the editors have gone far afield and have chosen men from all parts of the nation to write special chapters.

The volume is divided into four parts: section I on sociobiologic aspects, comprising three chapters; section II, clinical aspects, thirty-two chapters; section III, environmental aspects, six chapters; and section IV, organizational aspects, eight chapters. The selection of titles for the chapters is excellent and the whole field of preventive medicine is considered. As

always occurs in a book of this type, one encounters considerable variation in the quality of the material that is presented by the different authors. Some of the chapters have been written with the greatest precision and after a careful review of the subject; other chapters have been written more casually and without deep appreciation of the importance and value of available material. Furthermore, points of view and methods of presentation are sometimes at considerable variance. This is inevitable in a book of this type, as President Lowell once said, "Only one man can write a book." On the other hand, the multiple authorship gives the book a special value, since no one person could cover the enormous field of preventive medicine in an authoritative manner. The necessary unity and cohesion must be supplied by the editors—a difficult task, but one that has been well carried out.

The section on clinical aspects is the best. The whole purpose of the book is to focus the attention of medical men on the importance of incorporating preventive medicine in clinical practice. In this section, therefore, the authors have been most effective. It has been suggested that the other sections of the book might have been reserved for a second volume, which could be entitled "Public Health," for they deal more with community responsibility in health promotion than with the responsibility of the practicing physician in these matters.

The volume is well edited and beautifully printed. It does credit to its various authors and to the Academy of Medicine. The reviewer regrets that the book has one serious defect which may limit its usefulness as a textbook for medical students as well as a reference book for practicing physicians: its cost. Students, as a rule, are unable to purchase a ten dollar book, and practicing physicians do not yet appreciate the fact that it is well worth while to invest this sum in a book of this type. In this textbook the field is so well covered and the work so well done that, if studied carefully and referred to frequently, it will repay itself many times over.

Why We Have Automobile Accidents. By Harry H. DeSilva. Research Associate, Institute of Human Relations, Yale University, New Haven. Cloth. Price \$1. Pp. 331 with 33 illustrations. New York: John Wiley & Sons, Inc. London: Chapman & Hall Limited. 1942.

The American Medical Association has cooperated in every possible way with the authorities interested in cutting down the number of accidents occurring on the highways. Yet in this latest book on accident prevention, by a man who has done psychologic research in the field of traffic, almost no mention is made of the various committee reports and standards recommended by the American Medical Association. A wide variety of data are covered in this book from human engineering to mechanical engineering, from drivers' tests to the fiscal problems of highway building, which, while it has been covered adequately in a dispersed form in the periodical literature, has never been collected in a single volume. Such problems as speed on the highway, drivers' license testing, training of drivers and the factors involved in exposure to accidents are all systematically handled, but the human factors which interest the physician are not emphasized, probably because of the fact that the author is a psychologist and not a physician or psychiatrist. He has always been an advocate of mechanical testing of drivers, and the equipment which he built for this purpose has been exhibited at fairs and expositions. Yet in his book he frowns on that procedure and condemns it. While he stresses the driver, his emphasis lies on statistics rather than on the examination of persons, which is the *point d'appui* of the physician. No mention is made of the psychiatric examinations which have been made on thousands of drivers in psychiatric clinics connected with courts, although the clinics themselves are mentioned. The author does not recognize that psychobiologic mechanisms are important in traffic, i. e., that it is not speed which is important but the thinking processes which make the driver speed. Visual standards are only casually considered and then only from the points of view of visual acuity, tunnel vision and the effect of vitamins on vision. The book, which should have some value to traffic experts, has little for the physician who must decide on the basis of his examination whether the driver should or should not be permitted to continue to operate his motor car.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

EMERGENCY CARE OF FRACTURES AND SPLINTING

To the Editor—I have found a good deal of confusion in circulation with regard to the use of the Thomas or similar traction splint, to be applied as a first aid measure in connection with civilian defense in the event of an enemy air raid or bombing. The Office of Civilian Defense medical bulletin number 2 makes no provision for this traction splint at the first aid post but only at the casualty station. It is well known that E. M. Cowell, who introduced the Thomas splint drill in the British army during the last war reduced by this means a mortality from 70 to 40 per cent (in the field). The splint drill of the Royal Army Medical Corps training manual requires that the limb be splinted with traction before the patient is removed from the site of the injury. The slogan of the Committee on Fractures of the American Medical Association, "Splint 'em where they lie" is well known to those who visit the Scientific Exhibit of the annual sessions of the American Medical Association. My first question is: Why should not these traction splints be in the list of the equipment recommended for the first aid posts as recommended by the bulletin mentioned as well as for the casualty station as the latter is remote from the casualty and the first aid post is nearer the front line where the critical work is done? If the answer should be that the splints should be only at the casualty station or by preference please explain in full for it is not always a surgeon who passes on the purchase of supplies for this purpose. My next question is: Should a compound fracture with exposed bone be immediately treated in the field with a Thomas splint or similar traction splint? Several civilian surgeons have criticized this measure to me for the reason that in the compound fracture it would perhaps introduce sepsis if the end of the bone had penetrated the wound. Let us admit that the very nature of the casualty makes this a possibility and may require surgical debridement. The British instructions are not clear to me. Those I have read direct in case of a wound the cutting away of overlying clothing and dressing the wound and in case of severe hemorrhage of control of hemorrhage before splinting. The American Red Cross first aid book from which more than three million lay persons have had instruction (and hold certificates of proficiency—thus making them our critics) states that "The splint (Thomas) should be used for all fractures from the hip to the ankle . . . whether simple or compound" (p. 145). An even more explicit direction is given when the end of the bone protrudes (p. 137). "We are informed that in the last war about 30 per cent of all wounded men had compound fractures. This group is the largest of any major injury with which we have had to deal." We are informed of a definite change to a more serious character of the casualties of modern warfare especially among undisciplined civilian populations. Hook discusses the subject of fractures with protruding bone among the fractures resulting from the raid at Pearl Harbor where 48 per cent of the fractures were compound 39 per cent comminuted and only 13 per cent simple. He leaves the question of the application of the traction splint to be decided by the availability of definitive treatment. Thus, of course, would be a matter of surgical judgment and discretion the surgeon considering obviolous debridement not a part of Red Cross instruction. For the guidance of those physicians who are not actively engaged in traumatic surgery but who living in target areas must face tasks as well as the hazards of an open season for bombings an answer or an opinion on the furnishing of this splint to civilian first aid posts and what hazards result from its use would be most helpful.

Richmond C. Holcomb, M.D., Upper Dorby, Pa.

ANSWER—This well worded, pertinent query should be widely read and thoroughly understood by all physicians, for who shall say where the target areas may be located?

Traction splints should be an important part of the supplies furnished first aid posts and first aid teams sent to trouble spots. There should, however, be some one on hand who has had instructions in the art of application of the splint and fixed tractions for transportation. An uninformed person might easily add to the difficulties of the injured individual by rough, unwise or incautious movement of the injured leg, failing to recognize that the principal purpose is first applying gentle and continued traction in the long axis of the leg, to be followed by support in the splint and substitution of the hand held traction of an assistant by the fixed tied-in traction from the loop about foot and ankle. Practically all the traction splints used by the Royal Army Medical Corps in the first phase of this war were applied by the enlisted personnel on the field, hence the slogan of the Committee on Fractures of the American Medical Association.

Traction splints should also be available at the casualty stations, because unsplinted individuals will arrive at these points, but a traction splint should be supplied at once, on arrival there, before any attempt is made to carry the patient farther, even into the hospital station or to x-ray examination.

A compound fracture should be treated at once on the field with a Thomas or similar traction splint, even if bone protrudes

from the wound and its reintroduction into the soft tissues might carry in some infection. Such infection tends to remain local, it can often be controlled by the now universal use of the sulfonamide drugs spread onto the wound. Furthermore, such possible infection is probably not comparable in any way with the dangers of jarring, churning of bone in wounds, pain, increased hemorrhage and shock incidental to misguided efforts at transportation without a splint. All compound injuries are to be given debridement on reaching the casualty station or hospital where definitive treatment really starts. Hemorrhage at the site of injury may be controlled by firm pressure from sterile pack or dressing, rarely requiring use of a constrictor. On the fields of France many compound wounds thus splinted were transported for miles, and without the help of sulfonamide drugs. The results were as stated by the questioner. Debridement is not intended for Red Cross instruction—it is a surgical procedure.

SUBLINGUAL ADMINISTRATION OF MORPHINE

To the Editor—I am interested in getting information on the relative value of morphine sulfate given by mouth and by hypodermic. This subject is of great importance to medical officers who are working in the field.

M. Abrams, Mojor, M. C., A. U. S.

ANSWER—Morphine sulfate taken by mouth is completely and rapidly absorbed from the stomach and upper bowel. After absorption part of the morphine is excreted into the gastrointestinal tract. Morphine is quite rapidly destroyed in the body.

The sublingual administration of drugs offers a rapid route for the introduction of certain drugs into the systemic circulation. It is a much more direct route than through the stomach. The sublingual space is covered with a thin membrane of considerable extent. The network of large veins gives a free return of blood. In addition, the sublingual membrane is smooth, not furred like the tongue, nor is it covered with thick mucus or debris, as the stomach may be during a gastric upset.

When absorbed sublingually the drug escapes the action of the gastric ferments and, more important, it escapes the destructive action of the liver cells. In the case of morphine sulfate the liver through sulfonation causes a considerable loss in therapeutic activity.

If the mouth is too dry it may be rinsed with water. The hypodermic tablet or powdered drug is placed under the tongue just back of the teeth and the tongue is allowed to drop back into place. It is held in this position for a few minutes, although most of the drug will be absorbed in several seconds. The patient is advised not to swallow till the taste of the drug has disappeared. The effect will be felt quickly. The sublingual method of administering drugs has the advantage that it is quick, easy, safe, clean and reliable. It requires no special preparation, such as sterilization, and can be used by nonmedical persons.

Only those drugs which are effective in small doses, soluble and not irritating are suitable for sublingual administration. Morphine sulfate is ideal for this method.

RESISTANT THRUSH

To the Editor—A patient with thrush (*Oidium albicans*) has been having trouble for many months and it does not seem possible to clear the infection completely. Methylrosaniline 1 per cent has been applied faithfully. Are there any other substances which might be tried? A strong solution of silver nitrate was unsatisfactory. There is a liberal vitamin intake. I have wondered whether roentgen therapy is possible. The lesions are principally on the tongue but there is also some involvement of the buccal mucous membranes.

M. D. West Virginia

ANSWER—The failure of thrush (*Oidium albicans*) to clear with the use of methylrosaniline is fairly common. Roentgen therapy is not generally known to be effective but would be worth a try, as it is in many infections when other methods have failed.

Several methods have been found occasionally successful. They include the use of compound solution of iodine applied at least once a day to the infected areas in the mouth, the use of potassium permanganate solution of various strengths and the use of sodium sulfathiazole ointment in 1 to 2 per cent strengths. The first of these three methods has definitely produced results and the last of the three methods is fairly recent but recommended and could be combined with the parenteral use of sulfonamides (preferably sulfadiazine).

The patient should be known to have an adequate dietary intake, and the gums and teeth should be kept scrupulously clean without trauma. The presence of syphilis, tuberculosis of the lungs or an underlying carcinoma should be excluded by appropriate measures. This would be especially required if the patient is an adult.

POSSIBLE MUCOCUTANEOUS RELAPSE OF LATENT SYPHILIS

To the Editor—A man aged 48 who had been married twelve years developed a chancre following intercourse with his wife. She admitted having been treated with mercurial inunctions and potassium iodide (only) over a period of several months in 1922. There were no symptoms or treatments afterward, and she considered herself cured. Would she be able to transmit the disease at so late a date? What are the chances of obtaining a negative blood test from her? M D Illinois

ANSWER—It is not actually impossible that this patient, married for twelve years to a woman who had contracted syphilis eight years previously, contracted syphilis from her twelve years after marriage. The only likely circumstance, however, under which this might occur is the presumption that the woman developed an infectious mucocutaneous relapse twenty or more years after her own infection and, moreover, that she had not developed any such relapse until the twentieth year or later.

Ninety-five per cent or more of all infectious mucocutaneous relapses occur within the first four years of the infection. Late examples indeed as late as the twenty-fifth year have been reported but they are extraordinarily rare and they tend to occur in patients who are chronic relapsers that is who have had multiple relapses over a period of years.

The chance of "obtaining a negative blood test from her" depends entirely on the status of her own syphilitic infection (that is to say the presence or absence of neurologic visceral or osseous involvement), and the kind of treatment given. Generalizations are not possible.

SHOCK IN CORONARY THROMBOSIS—EXERCISE AFTER CORONARY THROMBOSIS

To the Editor—Having had a coronary thrombosis myself at a comparatively early age I write to ask two questions. 1. It is now clearly recognized that transfusions of blood or plasma are of greatest importance in combating almost all forms of shock whether associated with hemorrhage or not. Would not such transfusions be useful in the treatment of the shock associated with the early phase of coronary occlusion? Have they ever been tried? 2. According to the theory of Dr Timothy Leary the atherosclerosis which is a major factor in the production of coronary thrombosis is associated with fat metabolism. This would tend to agree with the common observation that coronary thrombosis is more common in those leading a sedentary life who do not burn up fat properly. Would it not be advisable therefore to increase rather than decrease the amount of exercise for those who have recovered from an attack of coronary thrombosis without anginal pain or any signs of decapensation in order to burn up the fat more completely? M D Colorado

ANSWER—1. It would not at first thought seem feasible to treat the shock associated with acute coronary occlusion with transfusions of blood or plasma because in this particular group of cases it is the involvement of the heart itself that is responsible for the shock. Usually that involvement is extensive if shock is produced, and at least some of the actual circulatory failure at such times is of cardiac origin. Hence to load the circulation up with additional fluid may unduly increase the work of the heart and precipitate further heart failure. It might however be cautiously tried out in certain cases if it could be shown that the shock in such cases is wholly vascular. Reports of such treatment have not been found.

2. Exercise in moderation after complete healing of myocardial infarction which has left no aftermath of serious cardiac enlargement or limitation of coronary or myocardial reserve is probably desirable in the effort to maintain a good general state of health as well as to help to control obesity and to prevent a sluggish peripheral circulation.

CHRONIC SEMINAL VESICULITIS

To the Editor—Is vasectomy of benefit in chronic unilateral nonspecific seminal vesiculitis? What role does a low grade stenosis of the duct have in nonspecific seminal vesiculitis? What therapeutic procedures or surgical procedures are indicated in stenosis of the duct? M D Georgia

ANSWER—As far as can be determined a vasectomy would not have any effect one way or the other on the progress of a nonspecific seminal vesiculitis. However a stenosis of the ejaculatory duct emptying into the posterior urethra has much to do with the chronicity of seminal vesiculitis and obviously an infected area without adequate drainage will not respond to any sort of management and the treatment, hence the dilation of the ejaculatory ducts with bougies. This is now being routinely done for this purpose and is the most common procedure now used for the treatment of seminal vesiculitis with duct obstruction. The old Belfield operation of vasostomy and injection of antiseptic substances which would reach the vesicle has not been popular of late and its benefits are considered doubtful.

Seminal vesiculectomy has been considered under these conditions and still is valuable as a surgical procedure of considerable benefit in carefully selected cases.

CIRCULATION TIME AND CARDIAC OUTPUT

To the Editor—On page 136 of the *Reader's Digest* for October 1942 it is stated that the blood travels the body circuit in seventeen seconds. Will you kindly tell me just how long it takes the blood to make the complete circuit and how much blood the heart pumps at each contraction?

George W. Reese, M.D. Sunbury Pa

ANSWER—The inquirer doubtless realizes that there is not any accurate way to determine total circulation time. Figures recorded vary with the technique used. One author gives twelve to twenty-eight seconds, average twenty-five seconds. Other authors give much lower figures, such as fifteen to seventeen seconds. The total time is of less practical significance than the time for limited parts of the circuit, such as arm to lung or arm to carotid sinus.

The heart ejects 3 to 4 liters per minute. At the average figure of 3,500 cc, at 70 beats per minute the stroke volume would be 50 cc. There are important qualifications on all of the statements. The inquirer should consult any good textbook on physiology for a fuller discussion than can be given here.

RADIOACTIVE STRONTIUM

To the Editor—Will you please give me any information you may have concerning the use of radioactive phosphorus or radioactive strontium in cases of multiple myeloma? Is it possible to obtain any at the laboratories?

W. T. Tharntan, M.D. Missoula, Mont

ANSWER—Radioactive strontium provides a means of giving selective beta irradiation to lesions of bone and bone marrow, since the element, like calcium, localizes in bone. Its use is in the experimental stage, and if and when it proves to be of great therapeutic value, it will become generally available. At present it is most readily made in a cyclotron, and there are several of these machines distributed throughout the United States, including those at the University of California University of Michigan, Ohio State University and Howard University. As far as is known no commercial laboratory handles the material.

OILS OF RETENTION ENEMAS

To the Editor—With the price of pure imported olive oil sky high is there any reason why pure domestic cottonseed or peanut oil should not be used for enemas in children? If so what can be substituted for olive oil?

J. J. Horton, M.D., Budo, Texas

ANSWER—There is no reason why the oils mentioned should not be used. Perhaps safer because nonallergic would be the ordinary hydrocarbon oil. Doubtless retention enemas are being thought of. For ordinary cleansing enemas, isotonic solution of sodium chloride is best.

REMOVAL OF NEEDLE FRAGMENT FROM DELTOID

To the Editor—I noticed on page 326 of the September 26 issue of *The Journal* note about a fragment of needle in the deltoid asking the best procedure for removal of the fragment if it is necessary to remove it. I agree that it is wise to leave the needle alone if it does not cause trouble, but if it becomes necessary to remove it the operation is by no means simple. I should like to offer some suggestions. When a foreign body is sufficiently large to be recognized under the fluoroscope its removal with fluoroscopic aid should be a simple matter. A puncture incision, perhaps a half inch in length, should be made at the site elected for the best approach. Then under fluoroscopic control a suitable forceps, preferably one with long jaws fairly narrow at the point, should be insinuated into the tissues through this opening in the skin in the direction of the needle. Fluoroscopic glimpses being made from time to time to show that the forceps is being pushed in the right direction. When the end of the retrieving forceps has approached the vicinity of the needle the x-ray tube should be rocked back and forth underneath the table while the movements of the needle and of the end of the forceps are observed on the screen (parallax method). It is important that the shutter be opened to provide a very small slit opening thus limiting to the minimum the illuminated area on the screen and thus protecting the hands of the surgeon. Naturally a sterile sheet or towel will be interposed between the screen and the surgical field. In the parallax method the object nearer the screen will undergo less movement than the object farther from the screen, thus it will be easy to know when the end of the forceps and the end of the needle are in the same plane, by rotating the patient to secure still further guidance one may grasp the end of the needle in the forceps and lock it, after which the forceps and the needle together can be withdrawn. If the surgeon is not accustomed to this method a little practice beforehand with a small needle fragment buried in an ordinary piece of meat will give him the necessary experience. This method has the advantage of necessitating only a puncture wound in the skin. A local anesthetic is sufficient. However it has been my experience that a small piece of a hypodermic needle broken off in the gluteal muscles is not easily visible on the fluoroscope especially in heavy persons. Under such circumstances the fluoroscopic method is probably inadvisable. A simple procedure consists in the introduction of two or three long straight needles into the part aiming at the region where the fragment of the needle is known to lie. Stereoscopic films may then be made and the relation of the foreign body to the guide needles determined. Then under appropriate anesthesia leaving these guide needles in place the offending hypodermic needle may be found without complication. I have usually found a local anesthetic adequate.

RENAL COMPLICATIONS DUE TO SULFADIAZINE

MAJOR DUWARD O. WRIGHT

MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

MAJOR ROY F. KINSEY

MEDICAL CORPS, ARMY OF THE UNITED STATES

The more recent literature concerning untoward effects of sulfadiazine on the kidney with at least one death testifies to the dangerous qualities of this drug. Early experimental and clinical reports were quite optimistic.¹ Trevatt, Nelson and Long² reported only 4 instances of hematuria among 125 patients given sulfadiazine. Billings and Wood³ treated 105 patients with pneumonia using sulfadiazine without a single renal complication. Finland, Strauss and Peterson⁴ reported only 3 cases of hematuria in a series of 446 patients treated with sulfadiazine. More recently Hellwig and Reed⁵ reported a case of fatal anuria following sulfadiazine therapy in which they described the pathologic condition in the kidney as being similar to that seen in mercury bichloride poisoning. Keitzer and Campbell⁶ reported 11 cases of renal irritation during and after sulfadiazine therapy. Four of their 11 cases required cystoscopy while the remaining 7 responded to conservative therapy. They concluded that sulfadiazine is safe with a dosage of 4 Gm a day and a blood level of not more than 8 mg per hundred cubic centimeters. Raines⁷ stresses the importance of daily quantitative and qualitative examinations of the urine.

During the six months that we have been using sulfadiazine here there have been numerous cases of renal irritation ranging from mild tenderness over the kidney to severe anuria. While we were using the other sulfonamides there were renal complications, but not as frequently as with sulfadiazine. The latter drug gives

one a false sense of security in that less toxic reactions in other systems are manifest in the patient.

Sulfadiazine has been used in the therapy of 38 patients during April, May, June and July 1942 in the infectious disease wards and the patients have been followed carefully. There were 7 instances of hematuria and we wish to report these cases in detail.

REPORT OF CASES

CASE 1—G. W. I., a white youth aged 21, was admitted May 8, 1942 for nausea and vomiting. With intravenous fluids and mild sedation the nausea and vomiting cleared, but the following day a headache and stiff neck developed and spinal puncture revealed cloudy fluid containing meningococci. Because of the previous nausea and vomiting he was given 5 Gm of sodium sulfadiazine in 100 cc of distilled water intravenously. One hour later he complained of severe abdominal and bilateral renal pain. On examination there was exquisite tenderness over both kidneys and some abdominal muscular spasm. In the following twenty-four hours he passed only 200 cc of grossly bloody urine containing innumerable red blood cells and many white blood cells but no crystals. During the second twenty-four hours the output increased to 700 cc and in the third twenty-four hours to 860 cc. The patient had received 2,000 cc of oral fluid and 2,000 cc of parenteral fluids within the twenty-four hours prior to the onset of symptoms, and his output had been approximately 1,100 cc. With the onset of symptoms fluids were forced intravenously and an attempt was made to alkalinize the urine. The renal tenderness, abdominal pain and hematuria disappeared on the third day and the urinary output reached normal on the fourth day. The meningitis was treated successfully with sulfanilamide and recovery was uneventful.

CASE 2—S. W. B., a white man aged 24 admitted May 22, 1942 for repair of a cicatrix on his right hand had an infection in the incision with an elevation of temperature and pain. On May 23 sulfadiazine therapy was started with an initial oral dose of 4 Gm followed by 1 Gm every four hours. On May 25 the patient had a mild microscopic hematuria with a sulfadiazine blood level of 7 mg per hundred cubic centimeters. The drug was withheld for twelve hours and the urine returned to its normal state; then the drug was resumed. Twelve hours later, after an additional 3 Gm, abdominal pain, nausea and vomiting appeared. The urinary output diminished and microscopic examination showed many red blood cells, a few sulfadiazine crystals and an occasional pus cell. Renal pain and tenderness developed but there was no severe colic. All physical and laboratory abnormalities disappeared within twenty-four hours on conservative therapy. The total dose of the drug was 12 Gm over a period of four days and the urinary intake during the four days ranged between 2,000 and 4,000 cc and the output 800 to 1,200 cc. During the twenty-four hours after the onset of abdominal pain the output fell to 75 cc.

CASE 3—E. R. S., a white youth aged 19, was admitted April 25, 1942 for multiple puncture wounds of the abdomen with multiple perforations of the small intestine and mesentery. Owing to the patient's critical condition the wounds were repaired under local anesthesia and a small amount of pentothal

sodium. The following afternoon respiratory distress developed, with cough, expectoration, a decided increase in the temperature and physical findings of either atelectasis or pneumonia in the right lower lobe. Examination of the sputum revealed large numbers of type XXIII and XXVIII pneumococci, and x-ray examination revealed consolidation of the right lower lobe but the findings were not typical of either pneumonia or atelectasis. Sulfadiazine therapy was instituted on the evening of April 27. Owing to the visceral trauma the drug was given intravenously in 3 to 5 Gm doses of 5 per cent solution in distilled water. Approximately thirty-six hours later, after 20 Gm had been given the blood level reached 15.4 mg, but at no other time did the level exceed 8 mg. On April 29 the level had dropped to 3.3 mg and the following day, April 30 microscopic hematuria developed with a blood level of only 5.6 mg. Because response to the drug had been good and the urinary output was more than adequate, an additional 3 Gm of the drug was given. After this the urine became grossly bloody and the output fell to 290 cc, less than one third of the previous day's output. The drug was discontinued and fluids were forced to 5,000 cc. Within seventy-two hours the hematuria and oliguria had cleared. With the hematuria there was exquisite tenderness over both kidneys, but it was difficult to determine whether this was due to his original wound or to the renal complications. It was assumed that the pain was renal since the tenderness became less pronounced as the hematuria cleared. His intake of fluids was more than 3,000 cc

TABLE 1—Fluid Intake, Urinary Output and Urinary Findings in Case 3

	Days After Onset of Hematuria									
	1	2	3	4	5	6	7	8	9	10
Nonprotein nitrogen	60				70		56			Normal
Urinary output

Day	1,350	3,650	3,500	2,650	2,540	2,900	3,205	2,720		
Night	1,500	1,145	480	380	600	100	200	700		
Albuminuria	Plus	Plus	0	0	0	0	0	0		
Cylindruria	Plus	Plus	0	0	0	0	0	0		
Hematuria	Plus	Plus	0	0	0	0	0	0		

and his output more than 1,000 cc prior to the onset of symptoms. The patient died on May 5 from hemorrhage and peritonitis. At autopsy the kidneys were normal.

CASE 4—E. S. K., a white man aged 22, was admitted May 1, 1942, with the diagnosis of concussion of the brain and multiple fractures of the ribs, with bilateral hemopneumothorax. The patient was recovering from his injuries satisfactorily when on May 11 pneumonia developed in the left lower lobe. Sulfadiazine was ordered on May 12, 4 Gm being given as the first dose and 1 Gm every four hours thereafter. With this dosage, the blood level remained below 4 mg per hundred cubic centimeters and there was no improvement in the pneumonia. On May 14 the dose was increased to 2 Gm every four hours and the sulfadiazine levels in the blood were as follows: On May 16 7 mg per hundred cubic centimeters, on May 17 5 mg, on May 18 3.6 mg and on May 21 8.5 mg.

Owing to the adequate blood concentration on May 21, and the pneumonia showing definite improvement, the sulfadiazine dosage was lowered to 1 Gm every four hours. At noon on May 23 the patient discovered large crystals in his urethral meatus and on the glans penis. The crystals were rather large, firm and orange-yellow and dissolved easily in warm alkaline solution. One hour later the patient complained of a burning sensation on the glans penis and, a few minutes later, of severe left renal colic and abdominal pain. Within an hour there was involvement of the right kidney and the pain radiated to the testis. He voided 120 cc of grossly bloody urine containing many large orange-yellow crystals. These crystals dissolved readily in the urine when it was warmed or alkalinized. In spite of forced fluids, heat to the back and abdomen and the administration of alkalis, the patient did not void again during the next eighteen hours. The nonprotein nitrogen increased from 38 to 44 mg per hundred cubic centimeters. The follow-

ing day as he was being prepared for cystoscopy he urinated 450 cc of grossly bloody urine, and cystoscopy was delayed. Conservative therapy was continued and the symptoms and signs abated after four days. The patient received more than 4,500 cc of fluids daily prior to the onset of symptoms, and the urinary output was 1,200 to 1,500 cc daily.

CASE 5—R. E. W., a white man aged 28, admitted June 7, 1942, complained of cough, expectoration and headache. A roentgenogram showed diffuse cottony infiltration throughout the medial half of the left lower lobe, including the region of the left costophrenic angle. After having a fever for four days he was started on sulfadiazine, being given 2 Gm at the first dose and 1 Gm every four hours thereafter. In all, he received 6 Gm during a period of two days. The urine was normal on admission and the output adequate, but on June 11, the day after sulfadiazine was started, the urine was grossly bloody and contained 2 plus albumin, a trace of acetone, many finely and coarsely granular casts, occasional epithelial casts, occasional pus cells and innumerable red blood cells. On June 12 the urine was essentially the same as on the previous day except that there was less albumin. On the following day, June 13, the urine was clear. The sulfadiazine level of the blood on June 12, twenty-eight hours after the last dose of the drug had been given, was 9 mg per hundred cubic centimeters. The urinary intake and output on June 9 and 10 were not measured but were considered satisfactory. After the onset of hematuria, the output fell to 625 cc.

Table 1 shows the patient's fluid intake, urinary output and urinary findings during the ten day period following development of hematuria.

During the morning of June 11, the intake was more than 3,000 cc, but the output was limited to 290 cc of concentrated grossly bloody urine. Although the drug was discontinued and alkalis and fluids were forced, the output was only 625 cc for the first twenty-four hours and only 100 cc for the following twelve hours. The urinary output was normal after seven days and the nonprotein nitrogen was normal after ten days. On June 12 and 13 there was some sacral edema.

The temperature, pulse and respiratory rates were elevated through June 13 and gradually returned to normal on June 14. A complete urologic work up was normal after recovery from the acute stage.

CASE 6—L. H., a white man aged 23, admitted May 21, 1942, had a severe productive cough and mild hemoptysis. X-ray studies, including instillation of iodized poppy seed oil, revealed only a chronic bronchitis. During the first four weeks of hospitalization he had a low grade fever and an elevated sedimentation rate, lost weight and expectorated 2 to 4 ounces (60 to 120 cc) of foul sputum daily. Since the sputum contained numerous mixed organisms with spirochetes and fusiform bacilli predominating, the patient was given 1½ grains (0.1 Gm) of neosarsphenamine June 21 followed by a moderately severe thermal reaction. The sputum diminished in amount and the odor was less foul, but the patient continued to have a low grade fever. On June 30 sulfadiazine therapy was instituted, the patient being given 8 Gm during the first twenty-four hours and 1 Gm every four hours for the following seventy-two hours. Because the blood level was 10 mg per hundred cubic centimeters, the dosage was lowered to 1 Gm every six hours, but the blood level remained at 10 mg and on July 6 the dosage was lowered to 1 Gm every twelve hours. The following day the blood level was again 10 mg and the drug was discontinued. The output of urine had been adequate and the urinary sediment normal except for sulfadiazine crystals and an occasional white blood cell. After the drug had been discontinued for eighty-four hours the patient suddenly had typical left renal colic and voided bright red bloody urine. The pain was so severe that morphine was required for relief, but it gradually cleared in twenty-four hours. Besides the innumerable red blood cells in the urine there were many white blood cells and orange-yellow crystals. The urinary output remained normal and the sediment returned to normal within forty-eight hours. A urologic work up was negative.

CASE 7—O. E. B., a white man aged 27, was admitted May 19, 1942, with meningococcal meningitis. Sulfadiazine therapy was initiated on May 19 by the intravenous route,

the first dose being 5 Gm in 100 cc of distilled water. Owing to the critical condition of the patient, an additional 4 Gm was given twelve hours later intravenously, the blood level being 56 mg per hundred cubic centimeters. Sulfadiazine was continued orally after this, being given in 1 or 2 Gm doses depending on the blood level. On May 21, the urine was normal with a blood sulfadiazine level of 8 mg per hundred cubic centimeters, but the following day there were large numbers of crystals. Painless hematuria developed on May 23 with a blood level of 10 mg per hundred cubic centimeters after 45.5 Gm of the drug had been given. There was moderate renal tenderness but no abdominal tenderness or renal colic. The urinary output and specific gravity remained unchanged in spite of innumerable red blood cells and crystals. The renal tenderness, hematuria and crystalluria cleared in forty-eight hours.

COMMENT

The tabulation of blood levels, dosages and duration of therapy prior to the onset of hematuria (table 2) emphasizes the inconsistency of these findings and does not render credence to their indictment as causative factors.

The average twenty-four hour intake prior to onset of hematuria certainly seems to be adequate. The average daily output for twenty-four hours is obviously low in comparison with the intake, which can be

trouble. Patient 2 was given a rest with disappearance of the hematuria only to have a recurrence with severe oliguria after an additional 3 Gm. Crystalluria was present in 4 cases before and during hematuria. Patient 4 had large orange-yellow crystals in his urethral meatus prior to onset of hematuria and renal colic. Crystalluria was present in case 4 eighty-four hours after administration of the last dose of the drug. It is difficult to explain the absence of crystalluria in 3 of these cases. It is our belief, in agreement with the pathologic report of Hellwig and Reed⁵ and the cystoscopic findings of Keitzer and Campbell,⁶ that there are two types of renal lesions, namely toxic effects on the tubular epithelium similar to those seen in mercury poisoning and mechanical blockage of urinary passages. Case 5 was probably due to toxicity, as there was a diminution of urinary output and an elevated nonprotein nitrogen for several days after the hematuria had cleared.

The specific gravity of the urine in our cases varied from 1.012 to 1.030 and in most instances ran from 1.016 to 1.022. The reaction of the urine was acid in all cases prior to hematuria. Schwartz, Flippin, Reinhold and Domm⁹ found fewer crystals in patients taking sodium bicarbonate.

TABLE 2—Blood Levels, Dosages and Duration of Therapy Prior to Onset of Hematuria*

Case	Blood Level Before Onset	Blood Level at Onset	Amount of Drug Given	Number of Days Drug Was Given	Average Daily Intake of Fluids Before Onset	Fluid Intake on Day of Onset	Fluid Intake on Day After Onset	Average Daily Urinary Output Before Onset	Output Day of Onset	Output Day After Onset	Crystals in Urine Before Onset	Crystals in Urine During Hematuria	Cylin-druria	Renal Pain	Abdominal Pain

* In all cases the urine before onset of hematuria was normal. Renal tenderness was present in all cases.

explained by the torrid climate. In a review of several cases in which sulfadiazine was given in the cooler months, it was found that the urinary output was much higher in proportion to the fluid intake than in the 38 cases in which sulfadiazine was given during the past four hot months. The average output did not equal the minimal of 1,500 cc recommended by Keitzer and Campbell,⁶ which seems to be the only constant finding prior to the onset of hematuria in these cases. However, this cannot be considered the only causative factor, because cases of renal irritation⁸ have been reported in which the urinary output exceeded 1,500 cc.

In some cases there is a gradual or sudden blood concentration of the drug which remains up regardless of diminution of the dose. This may be considered an indication for a rest period. Two of our patients, 5 and 6, had high blood levels on a dose of 2 Gm per twenty-four hours.

Abdominal and renal pain occurred in most of our cases and was considered an indication for discontinuing the drug. Renal tenderness was a constant finding prior to onset in all of our cases. It was known to be present in 2 cases six hours before hematuria.

From our experience, the appearance of even a few red blood cells in the urine is a sign of impending

The cases all responded to conservative therapy, although cases 2 and 4 were being prepared for cystoscopy before satisfactory results were obtained. Forcing of fluids—especially moderate amounts of distilled water intravenously—large doses of alkalis, heat to the back and abdomen and sedation are the essentials of our treatment.

CONCLUSIONS

1 Seven of 38 patients given sulfadiazine during April, May, June and July 1942 had renal complications.

2 The amount of the drug, the blood level, the duration of therapy, the fluid intake and the urinary output are not the only factors involved in renal complications from sulfadiazine therapy.

3 The urinary output was relatively low in comparison with the fluid intake in our cases. This is one of the most constant findings in these 7 cases.

4 Renal tenderness was present in all 7 cases and may prove a valuable warning sign.

5 The finding of even a few red blood cells, with or without crystals, in the urine is an indication that the drug should be withdrawn.

6 There are probably two types of renal damage, one due to mechanical blockage and the other similar to mercury bichloride poisoning.

⁸ Schulte, J. W., Shidler, F. P. and Neibauer, J. J. Acute Urinary Suppression Following Sulfadiazine Therapy. J. A. M. A. 119: 411-413 (May 30) 1942. Keitzer and Campbell.⁶

⁹ Schwartz, Leon, Flippin, H. F., Reinhold, J. G. and Domm, A. H. The Effect of Alkali on Crystalluria and Sulfathiazole and Sulfadiazine. J. A. M. A. 117: 514-515 (Aug. 16) 1941.

7 Most cases of renal complications from sulfadiazine therapy will respond to conservative measures if instituted early

8 The motive behind these comments is not an effort to decry the use of this valuable therapeutic agent but to emphasize the assiduous vigilance that is necessary to assure the safety of its use, particularly in the torrid climates and during the hot summer months in the temperate zone

COMPLETE ANURIA CAUSED BY SULFADIAZINE

ALEXANDER L. LOURIA, M.D.

AND

CHARLES SOLOMON, M.D.

BROOKLYN

Much has been written and said about the relative nontoxicity of sulfadiazine and the infrequency of its untoward effects, particularly with respect to renal complications. Indeed, very few cases of renal involvement have been reported. Two facts may account for this rareness, as pointed out by Feinstein, Williams, Wolff, Huntington and Crossley¹ first that the solubility of acetylsulfadiazine in the urine is much higher than that of the acetyl derivatives of sulfapyridine and sulfathiazole and, second, that sulfadiazine is not conjugated to the same extent as is sulfapyridine.

Finland, Strauss and Peterson² in their observations on a series of 446 patients treated with the drug noted 1 case presenting ureteral colic and gross hematuria which occurred on the seventeenth day of treatment with sulfadiazine. The blood concentration at that time was 198 mg per hundred cubic centimeters. The anuria that developed was relieved by catheterization and pelvic lavage. The first urine voided after catheterization contained 271 mg of sulfadiazine per hundred cubic centimeters, of which 150 mg was of the acetyl derivative. They also reported 2 cases that showed microscopic hematuria and 5 cases presenting elevated blood nonprotein nitrogen ranging from 15 to 26 mg per hundred cubic centimeters. In 35 of their cases crystals were found in the urine, the crystals had the appearance of sheaves of wheat and resembled the crystals of acetylsulfathiazole.

Thompson, Herrell and Brown³ observed complete renal suppression in their sixteenth patient treated with sulfadiazine after the administration of 675 grams (about 44 Gm.) of the drug over a period of seven days. It is interesting to note that during the course of sulfadiazine administration the urine was alkaline in every specimen except one.

Bradford and Shaffer⁴ described the pathologic changes in the kidneys in their case of fatal sulfadiazine anuria. The patient received 24 Gm of sulfadiazine during the first five days, then none for fifty hours, then 26.5 Gm during the second course, making a total of 50.5 Gm administered to the patient. Sulfadiazine

was stopped on the twelfth day because the urinary output diminished to an alarming degree, the urinary output ceased for forty-eight hours preceding death.

Raines⁵ claims that he had seen several patients in whom sulfadiazine obviously caused damage and in 1 instance death. In the fatal case a man aged 69 passed a blood tinged urine seventy-two hours after the beginning of sulfadiazine therapy. On the third day after admission the patient complained of pain in the lower part of the abdomen and then stopped voiding. The left ureter was catheterized and four days after the onset of anuria the right ureter was catheterized but to no avail.

Hellwig and Reed⁶ also reported a case of fatal anuria following sulfadiazine therapy, claiming that death was due to renal failure. The total amount of drug given during nine days was less than 24 Gm. Cystoscopy with irrigation of the renal pelvis and ureters, intravenous administration of fluid and alkalinization were without success. The kidneys showed severe degeneration of the convoluted tubules similar to that seen in mercuric poisoning.

The 5 instances of complete anuria referred to are the only ones that have been reported up to the present time. Cases of partial urinary blockage have been noted. Wheeler and Plummer⁷ used sulfadiazine and sodium sulfadiazine in a series of 218 cases. Among those receiving sulfadiazine, 2 patients complained of pain in both flanks and showed gross hematuria, another patient had gross hematuria but no pain in the flanks. Among those receiving sodium sulfadiazine, 2 patients complained of pain in one flank and showed gross hematuria, the pain was never severe and disappeared in twelve hours. The gross hematuria cleared up at the end of twenty-four hours. No permanent renal damage occurred. Urinalysis and renal function—as determined by the ability of the kidneys to concentrate and the urea clearance test—were normal within a few days of the time that the reaction occurred. Some of their patients during the course of treatment showed a slight or moderate increase in the number of red blood cells on microscopic examination of the centrifuged sediment. This hematuria was usually found in association with a considerable number of crystals of the drug in the urine. This finding, they believe, is no indication to stop the drug, when the drug was continued, no ill effect was observed.

Dingle, Thomas and Morton⁸ treated 14 cases with sulfadiazine, in 2 of these pain occurred. In 1 pain over the right ureteral distribution developed on the eighth day of treatment and lasted several hours. The urine voided at this time showed from 10 to 15 red blood cells per high power field and numerous sulfadiazine crystals in the uncentrifuged specimens. In the other case pain occurred in the right flank. This pain, associated with microscopic hematuria, developed on the eighth day of treatment, but no sulfadiazine crystals were found in the urine. The urine in both cases cleared rapidly after cessation of chemotherapy.

Further evidence of the rarity of anuria in patients treated with sulfadiazine is attested by Dowling, Hart-

From the Medical Service of Dr. Alexander L. Louria, Jewish Hospital of Brooklyn.

man, Sugar and Feldman,⁹ who found no instance of renal lithiasis in a series of 137 patients treated with the drug. Sulfadiazine crystals were found less frequently in the urine than sulfapyridine or sulfathiazole crystals during administration of the latter drugs in similar doses. The blood urea nitrogen of 2 patients was increased but remained below 50 mg per hundred cubic centimeters. It was difficult to determine whether this mild azotemia developed as a result of the disease or of the administration of the sulfadiazine. Styron, Bromley and Root¹⁰ found no case of gross hematuria in their series, 2 cases in which there was increased nonprotein nitrogen they attributed to glomerulonephritis. They used sulfadiazine and sulfathiazole on 200 nondiabetic and 100 diabetic patients. Their report does not make clear which patients received sulfadiazine and which sulfathiazole. Among 100 patients treated with sulfadiazine by Flippin, Rose, Schwartz and Domm,¹¹ microscopic hematuria was observed in 4, no patient had gross hematuria and 29 per cent had urinary crystals. Reinhold, Flippin, Schwartz and Domm¹² found no renal complications among 24 patients treated with sulfadiazine.

In answer to a question regarding the significance of the presence of crystals of the drug in the urine the answer was as follows: "The appearance of crystals in the urine of a patient who is receiving sulfapyridine, sulfathiazole or sulfadiazine is not of special significance unless the crystals are accompanied by microscopic or macroscopic hematuria. While it is not a good practice routinely to administer sodium bicarbonate with sulfapyridine, sulfathiazole or sulfadiazine, it would appear from the work of Schwartz and his associates (*THE JOURNAL*, Aug 16, 1941, p 514) that under certain conditions the maintenance of high alkalinity of the urine will decrease the amount of crystals in it."

The following case is the sixth known recorded case of complete anuria resulting from sulfadiazine therapy.

REPORT OF CASE

B B, a white woman aged 25, unmarried was in the Jewish Hospital at Brooklyn from May to July 1940 at which time a diagnosis of rheumatic heart disease was made. Following discharge she indulged in ordinary activity and was fairly comfortable until three weeks prior to readmission to the hospital. During this period she complained of sweats and feverish sensations. Her temperature was found to be 102 F and she was put to bed and given salicylates. However, the temperature remained elevated during these three weeks and she was brought into the hospital on March 18, 1942. Physical examination at this time revealed that the patient was orthopedic, pale, cyanotic and acutely ill. Her temperature was 102.4 F, the pulse 112 a minute and respirations were 20 a minute. Several small petechiae were found in the conjunctivas of both lower eyelids. The eye grounds showed nothing abnormal. Several petechiae were seen under the breasts. The heart was slightly enlarged to the left and double mitral and aortic murmurs were audible on auscultation. The spleen and liver were not palpable and physical examination was otherwise negative.

Laboratory examination gave the following results. The blood count, March 18, showed evidence of a mild secondary anemia with hemoglobin of 74 per cent, red blood cells 3,600,000 and white blood cells 8,800, with 74 per cent polymorphonuclear leukocytes. At times the hemoglobin dropped to as low as 50 per cent, and a few transfusions were given. On March 28 examination of the urine showed a specific gravity of 1.018, tests for albumin, sugar and acetone were negative and an occasional red blood cell was present in the sediment, which also contained some acetylsulfadiazine crystals. The Kline test was negative, a blood culture taken on admission of the patient to the hospital yielded 56 colonies of *Streptococcus viridans* per plate.

Therapy consisted of the administration of sulfapyridine 2 Gm (30 grains) followed by 1 Gm (15 grains) every four hours. This had to be stopped after twenty-four hours because of profuse vomiting. Sulfathiazole in the same dosage was started two days later and was given for two days. This drug also had to be discontinued because of vomiting. On March 26, the eighth day of hospitalization, sulfadiazine therapy was begun. 2 Gm was given followed by the same amount in two hours and then 1 Gm every four hours. After five days of apparent tolerance to the drug, during which time there was no effect on the fever she voided only 150 cc of urine. The drug was stopped immediately but complete anuria occurred all through the following day. The blood concentration on the day the drug was discontinued was 224 mg total sulfadiazine per hundred cubic centimeters. Cystoscopy was performed the next day, a 21 F cystoscope being passed easily. The bladder contained 2 cc of cloudy urine. There was slight congestion throughout the bladder, more noticeable in the region of the left ureteral orifice, which was also edematous. A crystalline deposit was present in the right ureteral orifice. A small concretion about 2 to 3 mm in diameter was found on the floor of the bladder. A no 6 F catheter could not be passed into either ureter, but a no 5 F was introduced for a distance of 28 cm into the right renal pelvis. No drainage occurred. After irrigation with several cubic centimeters of warm saline solution a moderately active flow of slightly sanguineous urine appeared. Attempted catheterization on the left side was unsuccessful until a no 5 olive tipped catheter was used, which permitted an efflux of crystals as the ureter was entered. The catheter was then advanced 28 cm to the pelvis of the kidney. No return was obtained until an irrigation with warm saline solution was done. The flow was active and the urine clear. The two catheters were left in situ for seventy hours during which time the urine dropped freely. After removal of the catheters the patient's bladder had to be catheterized once. Thereafter she voided freely. The day after the drug was discontinued the blood concentration was 89 mg per hundred cubic centimeters and declined steadily to 3 mg per hundred cubic centimeters on the fifth day. Two days after the sulfadiazine was started crystals were found in the urine, which, however, showed no other abnormalities. No hematuria, hemolysis or other untoward effect was noted. After sixteen days had passed without chemotherapy, sulfadiazine was again started on April 17. For the first two days 5 Gm (75 grains) was given in twenty-four hours. The dose was then increased to 6 Gm (90 grains) daily until May 11, when the drug was withheld because nausea and vomiting appeared. The urinary output remained adequate, examination of the blood on May 11 showed hemoglobin 53 per cent, red blood cells 3,200,000 and white blood cells 10,200, with polymorphonuclear leukocytes 75 per cent. Concentrations of the drug in the blood (in milligrams per hundred cubic centimeters) on various determinations from April until May 11 were 98 total, 93 free, 74 total, 72 free, 67 total, 63 free, 125 total, 119 free, 59 total and 77 total. The patient also received seven intravenous injections of typhoid vaccine in doses ranging from 1 to 9 minims (0.06 to 0.55 cc). A similar response occurred with each injection, the temperature rose to and was maintained at 106 F for several hours. Her urinary output was adequate and there was no evidence of hematuria, either microscopic or gross.

CONCLUSIONS

Review of the literature and our own experience seem to warrant the following conclusions

1 If the urine output is good, the presence of crystals in the voided urine output should not be considered an indication for discontinuing the drug

2 The appearance of gross blood in the urine at any time during administration of the drug should be an indication for discontinuing the drug

3 Hematuria clears up promptly after the drug has been stopped

4 No permanent renal damage has been observed in the cases in which recovery has been reported

5 Obstruction of the urinary tract resulting from the deposition of crystals of the drug may be relieved promptly by ureteral catheterization and pelvic lavage

6 Whether alkalization of the urine will deter crystal deposition in the urinary tract is still a moot point

LESIONS OF THE RIGHT COLON INVOLVING RIGHT COLECTOMY

FRANK H. LAHEY, M.D.

AND

ERIC SANDERSON, M.D.

Fellow in Surgery the Lahey Clinic
BOSTON

Out of an experience of 170 resections of the right colon and terminal ileum, of which 112 were for carcinoma, 53 for regional ileitis, 4 for tuberculosis and 1 for endometriosis, have come some deductions and conclusions which to us have been of value. These will largely relate themselves to two conditions, that of carcinoma of the right colon and that of regional ileitis since the experience with tuberculosis in this group is too limited from which to draw conclusions, and the single case requiring resection of the right colon for endometriosis was solely the mechanical problem of angulation and obstruction as the result of inclusion of the terminal ileum with the right colon in the endometrial implants.

CARCINOMA OF RIGHT COLON

In the diagnosis of carcinoma of the right colon we, as has every one else, have been impressed with the fact that severe grades of secondary anemia are associated with malignant lesions at this level more than at any other level. Lest any one think, however, that this anemia is consistently present with carcinoma of the right colon, an investigation of our records shows that in not over 70 per cent of the cases have there been really severe grades of secondary anemia. It is, however, so characteristic of this lesion that, when we see a patient with a pallor and lemon yellow color so often associated with these severe grades of secondary anemia, who in his history even before being examined complains of right abdominal discomfort, we immediately become suspicious of a malignant lesion of the right colon. In addition to this, we would urge that the grades of secondary anemia which can be present with malignant lesions of the right colon with

the lesion still removable and in many cases not recurring over long periods of time do not exist in lesions of the left colon, rectosigmoid and rectum in the absence of metastatic extension which marks the lesion as inoperable. One can, therefore, assume the possibility, more in a malignant condition of the right colon than in the left, that even in these advanced grades of secondary anemia with lesions of the right colon, the lesion may still be removable at a stage when nonrecurrence is at least a probability.

No one has ever as yet adequately explained why a relatively small lesion of the ascending colon can produce such severe grades of secondary anemia. Suggestions such as that made by Alvarez of the anemia being related to the diameter of the ulcerating lesion, and so the amount of absorption from it, the suggestions by others as to the constant leakage of blood and the suspicion by one of us (F. H. L.) of the relationship of the absorption of toxins and organisms in the liquid mediums of the right colon are of interest but by no means adequately explain the striking association of these high grades of secondary anemia with this particular lesion.

It is unfortunate that the diagnosis of carcinoma of the ascending colon is unassociated with early and distinctive symptoms. Since it is our conviction as the result of our experience with malignancy in polyps that a great many of the malignant lesions of the colon and rectum originate in adenomas or polyps of those structures, it is obvious that they start at one point and so do not produce particularly here where the contents of the bowel are liquid, obstructive symptoms until they have been present for a considerable period of time. It has been roughly estimated that, if a malignant lesion starts at one point on the bowel, it requires from six months to a year, allowing that range for variation in rate of growth, to encircle completely the bowel and produce obstructive symptoms. Except when a malignant lesion of the ascending colon happens by chance to occur at the ileocecal valve, the liquid contents of the bowel at this point plus the large diameter of the cecum, ascending colon, hepatic flexure and right transverse colon are such that early obstructive symptoms are rare. It is unfortunate also that the leakage of blood from such a lesion mixes itself intimately with the liquid feces here and so unless of considerable quantity, does not diagnostically reveal itself early in the stools as does blood from the left colon, sigmoid, rectosigmoid and rectum.

It is likewise unfortunate that the mere presence of an ulcerating lesion in the right colon, until fairly well advanced and involving other structures, causes so few symptoms and such little inconvenience. It is further unhappily true from the aspect of possible early diagnosis that such is the caliber and size of the cecum and ascending colon that lesions, particularly on the posterior wall, can fail to demonstrate themselves in the barium filled cecum and can be easily overlooked by the roentgenologist.

As to the histories of carcinoma of the right colon, one can only say that the same features are to be looked for in malignant lesions at this level as at other levels in the colon—the presence of blood, gross or microscopic, mucus, change in bowel habits, anemia, loss of weight and vague abdominal symptoms.

It is additionally unfortunate that malignant lesions of the ascending colon, cecum and hepatic flexure tend to be less palpable through the abdominal wall than

do lesions of the sigmoid, rectosigmoid and rectum. It has been our experience, dealing now with an operative experience amounting to over 1,300 lesions of the large bowel and rectum that have been operated on, that in carcinomas of the sigmoid, rectosigmoid or rectum more than half of the lesions are palpable either through the rectum or through the abdomen, while lesions of the right colon are as a rule not palpable.

While the difficulties of early diagnosis is the result of the foregoing facts are true, rarely will carcinoma of the ascending colon be present in the absence of the demonstration of occult blood in the stool, and rarely will it be impossible, by careful and repeated fluoroscopic examinations and lateral roentgenograms of the colon showing posterior wall lesions, to diagnose carcinomas at this level.

Nothing that we have learned in this experience has been more important than that one should appreciate the fact that in the past many of these cases have been regarded as inoperable and the wound has been closed when the lesions involved other structures only in the form of contact extension and not true metastases, producing inoperability.

Carcinomas of the ascending colon are particularly prone to involve the ileum or jejunum by contact metastases and we have repeatedly found it possible in cases with such contact metastases to do multiple level resections successfully, resecting the ascending colon and a segment of the jejunum or ileum. In several such cases the lymph glands of both structures have been found uninvolved in the malignant growth and there has been nonrecurrence over several years. Since some of these cases have been regarded as inoperable elsewhere and the wound closed because of these contact metastases, before being sent to us, we are led to express again what we have repeatedly preached and written, that is, that one must be extremely careful in deciding whether or not a malignant lesion of the large bowel is inoperable, as to whether the extension is that of a contact character or of metastases into adjacent lymph nodes or involving such structures as are nonremovable.

Lesions of the right colon are particularly apt to involve the lateral peritoneum and lateral abdominal wall by contact extension. We have a number of times removed such lesions together with the lateral peritoneum to which it was adherent and even the local musculature of the abdominal wall, leaving the wall covered only by skin and subcutaneous fat. It has been necessary in some of these cases with large local lesions particularly in the malignant growths around the hepatic flexure, to do complete dissections of the kidney pelvis with its entering ureter and vessels or, as occasionally has been the case, to remove the kidney with the lesion to which it was adherent. It has been occasionally necessary likewise to do cholecystectomy because of the involvement in the exudate or by the growth of the gallbladder in the malignant mass. Occasionally carcinomas of the ascending colon or hepatic flexure will attach themselves to the under surface of the liver by direct contact. It is not to be assumed likewise that lesions here are inoperable, since by means of the cutting current it is possible to excise that section of the liver only locally involved in the malignant lesion by direct contact, to suture its bed or to control the oozing satisfactorily by packs, and to accomplish radical removal of that section of the colon with its contained

growth. It is obvious from these cases that this group of cases does not represent a selected group but rather one in which range of operability has been extended to its maximum.

In the operative removals of carcinomas of the right colon by the modified Mikulicz operation which we have now employed over a number of years and which one of us has described (F H L), it is important to state, because of the confusion which exists in many minds about the old and original type of Mikulicz operation and the modern modification, that the procedure in no way differs in the extent of its radicalness, either in amount of colon removed or in the area of adjacent mesentery and mesenteric glands included in the removal of the colon. It differs from primary removal and primary anastomosis only in the method of restoring the fecal stream and not in radicalness of extent. Any discussion, therefore, of the extent of removability, the extent of colon or mesentery removed applies equally to any medical method of removing this segment of large bowel.

As a result of our experience with this procedure, we have become convinced that it is important after the right colon has been mobilized by incising the lateral leaf of peritoneum outside the colon and turned inward,

Fig 1—*a* diagrammatically demonstrates the amount of ileum ascending colon and transverse colon to be resected the dotted lines indicating the radicalness of the extent of removal of attached mesentery and glands. In *b* the lateral parietal peritoneum has been incised the colon turned inward the ileum and transverse colon divided between clamps and the mesentery severed up to its root. It is to be noted that the duodenum has been separated from the root of the mesentery and held upward and that the ureter has been retracted outward, thus permitting the extensive removal of mesenteric root to the midline.

to find at once behind the rotated colon either the ovarian vessels in the female or the spermatic vessels in the male and then the structure from this toward the middle line, the ureter. The ureter is freed from its attachment to the posterior parietal peritoneum covering the inner side of the mesentery of the ileum and colon as it passes over the brim of the pelvis, and followed upward to its position behind the duodenum where it enters the kidney pelvis and is clearly visualized throughout its extent. It is important, we believe, to mobilize the ureter throughout its entire extent so that a large leaf of mesentery running from the terminal ileum up to the apex of the V of right mesentery which is to be removed can be freed. It is next important, we believe, to dissect carefully the retrocolic duodenum well off from the root of the mesentery, since only by completely freeing the hepatic flexure, turning it inward and completely freeing the retroperitoneal duodenum will it be possible to extend the removal of the mesentery of the right colon sufficiently close to its root in the midline to remove adequately all of its contained nodes (fig 1 *b*).

because we believe that by this method we can most effectively remove the infected segment of bowel and with it the infected glands in its attached mesentery. We have been impressed with the desirability of carrying this radical plan of treatment in this lesion because there has been but one death in the 53 resections and that in the presence of an abscess and perforation. Particularly because in spite of such radical resections, there have been but 2 cases in which the disease has recurred in the remaining ileum. These recurrences took place in the beginning of our experience when we did removals of the ileum but with limited resections of the ascending colon, thus leaving infected glands in the remaining areas of attached mesentery. Since we have done more of these operations we have realized that the infecting process not infrequently extends over onto the ascending colon for varying distances so that it is desirable to resect not only

serving as a spigot for immediate decompression. This operation lends itself just as satisfactorily to all resections of the right colon as presented in this group of cases as it does to carcinoma of the right colon.

As a result of this experience, we have set up for ourselves certain rules to apply in cases of regional ileitis. One is that there is definitely a stage with red, acutely inflamed ileum covered with fibrin in which we would prefer not to resect. It is at this stage that the peritoneum has not yet vaccinated itself well to the infection. It is at this stage that the inflammatory reaction within the mesenteric glands is acute and so makes them more difficult and less desirable to handle. Fortunately, it is at this stage so often that the patient has been operated on before coming to us under the mistaken diagnosis of acute appendicitis and nothing more than the appendix has been removed. This has been true in 25 per cent of the cases in which we have operated. This is fortunate, as it permits the patients to have vaccinated their peritoneal cavity well to the lesion and the lesion to have become less acute and more of chronic character. We have assumed the position that if these patients are to be operated on it is desirable when possible, as has usually proved to be the case, to remove radically all the segment of infected bowel together with this adjacent mesentery and infected mesentery glands, as shown in figure 1a. We have realized the possibility of other segments of bowel being involved and have always insisted that the other levels of small intestine be investigated to make sure that other segmentally involved areas do not exist.

In any discussion of resections of the right colon by the employment of the plan of modified Mikulicz resection, it seems wise to discuss briefly some of the points particularly related to the successful second stage closure of the Mikulicz enterostomy after the spur has been cut.

We were interested in the beginning of our experience with this operation to have these patients back for closure of their temporary external ileocolostomy as early as possible, since they were never happy as long as even part of their feces was discharged through the temporary external ileocolostomy. In addition to this, many of those patients have had varying degrees of skin irritation about their temporary external ileocolostomies. We have become more and more convinced with the widening experience with the secondary closure of Mikulicz external ileocolostomies that it is wise not to attempt to close them earlier than two months after operation. If one attempts closure before this time the wound is often still edematous, there are small fluid pockets of undigested catgut in it and the peritoneum has not become firmly fixed to the neck of the intestinal spur. We have therefore taken the position that all these patients shall wait for two months before returning for their second stage closure. At the beginning of our experience we were often hesitant to do these secondary closures when there was considerable skin irritation about the external ileocolostomy of a right colon Mikulicz resection. We have now learned that

much skin reaction there is they can and that, since this reaction is of a toxic nature, as soon as the patient appears and promptly in all probability the tissues and that place even when

Figure 1a. Typical string sign of Crohn in regional ileitis. Note also extension of the process onto the colon.

Not infrequently a segment of ileum but also all of the ascending colon, with the hepatic flexure together with its mesentery transverse, as wider resections have been done there have been recurrences. As shown in figure 3a, one of the advantages of the terminal ileum and right section of the transverse colon with such an extensive mesentery with its infected region. We have been particularly, if limited sections are often leaves behind infected mesenteric glands.

In dealing with one will occasionally perforated and is possible with a modification shown in figure 2d satisfactorily. By between clamps, the

first described and illustrated in figure 3b, to insert a catheter or a Paul tube into the end of the ileum immediately at the time of operation connect it by a rubber tube to a bottle beside the bed and accomplish immediate decompression of the small intestine. There is nothing more important, we believe, in any intestinal

Fig. 4—Involvement in regional ileitis of all the coats of the ileum

resection than the ability to decompress at the time the resection is done. Patients sometimes die following colon resections not because of the resection itself necessarily but as the result of the temporary obstruction which goes with it and the effect of this on their general condition and the suture line. It is to be noted in figure 3b that the loop of ileum into which the tube is inserted has been devascularized and will slough off even with the abdominal wall, thus resulting in a double barreled intestinal loop, the ends of which are at the same level on the abdominal wall.

The clamp on the spur of the Mikulicz loop is applied on the sixth to the seventh day, and it has been our experience that it is better to apply the clamp two or three times than to attempt to cut the septum of the spur with one long clamp. We fear the danger with the long clamp of including too much in the bite of the clamp and we believe that the hazard of perforation with such a long clamp is greater than with two or three small bites.

Of all the patients with carcinomas of the large intestine having resections in this clinic followed over five years, 43 per cent of those with carcinoma of the rectum and 57 per cent of those with carcinoma of the colon on whom the radical operation has been done have remained alive and well over that period of time without recurrence. The nonrecurrence rate in the carcinomas of the right colon have averaged at the same rate as have the carcinomas of the colon at other levels.

REGIONAL ILLITIS

The other condition which we wish to discuss is that of regional ileitis. There is little to be said concerning the cause of regional ileitis except that any lesion of obvious inflammatory character, which on microscopic examination demonstrates itself as inflammatory in nature by the round cell infiltration which is associated with it, and which involves, as does regional ileitis, all the coats of the bowel (fig. 4) must be assumed to be inflammatory even though the infecting agent cannot be demonstrated. It seems reasonable,

therefore, to conclude that regional or terminal ileitis is an inflammatory reaction to an agent not microscopically demonstrable. In all of these reported cases the lesion has been limited to the terminal ileum. It has been quite consistent in character, in symptoms and in appearance, varying only for practical purposes as to the complications associated with it, largely the result of perforations or mechanical obstructions, perforations which have produced local abscesses or sinuses by perforating into adjacent viscera.

The diagnosis has been based on the history of right lower quadrant pain, not infrequently diarrhea, and intermittent obstruction associated with it, chronicity of the history, weight loss and not infrequently a previous operation such as appendectomy, without relief. Palpable masses have occasionally been present and external and internal fistulas have been demonstrable in 25 per cent of the cases, so that whenever a patient comes to us with a history of having been operated on for appendicitis, followed by a chronic fistula, particularly when associated with intermittent obstructive symptoms, we are extremely suspicious of regional or terminal ileitis.

It has been possible in a large percentage of the cases to demonstrate the rigid ileum, as shown in figure 5, and in many others the typical "string sign" described by Dr. Burrill Crohn, as illustrated in figure 6.

The discussion of the treatment of regional ileitis is concerned with (1) whether it is to be treated expectantly and if so what can be done, (2) whether it is to be treated surgically in a conservative manner by lateral anastomoses as has been advocated by some or (3) whether it is to be treated by a radical removal of the involved ileum and adjacent colon as we have employed, and what the results have been.

We know of no medical measures which can be applied to this disease that offer any prospect of limiting its extension. Not only is this true, but while one applies medical measures it is possible for the process

Fig. 5—Gross specimen of regional ileitis removed showing extension to the ileocecal valve, the infiltration of all the coats and stricturing near the ileocecal valve.

to involve adjacent structures, such as the sigmoid, to perforate into these adjacent structures and form sinuses into the sigmoid, bladder, vagina and externally as had already undeservedly occurred in many of these cases when sent to us for operation.

We have deliberately applied radical resection of ileum, ascending colon and hepatic flexure to

We have found it desirable in resections either of the terminal ileum or of the right colon to include in the resection all of the ascending colon, the hepatic flexure and the right portion of the transverse colon. This is desirable because it permits wider resection of the mesentery of the right colon and hepatic flexure (fig 1a) with its contained glands and because the

Fig. 2—*a* method of dealing with carcinoma of the ascending colon with abscess. Note that the transverse colon has been severed between clamps as has the ileum but that the abscess is not opened and the ascending colon removed until the mesenteric root of the Mikulicz resection has been sutured thus segregating the general peritoneal cavity. With gauze packs about the bowel the segregated section of colon with the abscess can be dealt with the abscess sucked out and the carcinoma containing colon removed. *b* long approximation of ileum to transverse colon in order to make a long spur to cut. In *c* the segregated section of bowel containing the carcinoma with abscess shown in *a* has been removed the abscess cavity dried out filled with sulfanilamide and packed with gauze and the end of the drain is shown emerging through a counter incision.

ileum can be applied more satisfactorily to the transverse colon, placed as it is in a straight line, than to the angulated, often reduplicated, hepatic flexure. This makes a very much better and accurately opposed Mikulicz double barreled tube than does the application of the ileum either to the ascending colon or to the hepatic flexure.

We have done so many Mikulicz resections of the right colon now that we have learned how to overcome most of the difficulties that may be associated with this procedure. One of the very important things is to be sure that a much longer loop of ileum is tacked, as shown in figure 2*b*, to the transverse colon than one thinks is necessary. It is of no disadvantage whatever to tack too much ileum to the transverse colon, but it is of considerable disadvantage to tack too little. Not infrequently in tacking the ileum to the transverse colon, when radical removals of the right half of the transverse colon have been done it is found that an insufficient amount of transverse colon can be pulled up into the wound. This can always be easily remedied by freeing the gastrocolic omentum to the left transverse colon, by liberating the attachment of the splenic flexure, lowering it and making available longer loops of transverse colon to be pulled into the wound. One can, if necessary, so liberate the splenic flexure that the descending colon can be brought into a right rectus incision, with the establishment of a double barreled loop by applying the terminal ileum to its side.

In dealing with resections of the ascending colon one will occasionally encounter a carcinoma which has perforated and is surrounded by an abscess. It is possible with a modification of the Mikulicz procedure, shown in figure 2*a*, to deal with this quite safely and satisfactorily. By this plan the transverse colon is cut between clamps, the ileum is cut between clamps and

the mesentery is severed but the adherent ascending colon with the carcinoma and abscess about it is not removed. The root of the mesentery as shown in figure 2*a* is carefully sutured, thus excluding the small intestine and serving as a coffer dam. With gauze packs about the segregated section of ascending colon containing the carcinoma and the abscess, walling off the rest of the abdomen, the abscess can be entered, sucked out, drained, the colon removed and the abscess cavity thoroughly dried out, filled with sulfanilamide and packed with gauze. The gauze surrounded on its external portion by rubber dam can then be brought out through a counter incision as shown in figure 2*c*, and the Mikulicz loop implanted in the wound.

One of the things one must have in mind in resections of the right colon is that the parietal peritoneum in the jejunal fossa at the region of the ligament of Treitz is often thin and that the entrance of the jejunum retroperitoneally can be high up in the mesentery of the right colon. As the colon is mobilized and its mesentery freed so that it hangs by its root in the middle line, one must be careful as the mesentery, seen from behind, is cut down to a V that the loop of jejunum, often toward the right, be not included in the clamps, and that an adequate amount of peritoneum is left adjacent to it so that a defect is thus left in the mesentery root which cannot be repaired. Should such a nonrepairable defect remain, it can permit the occurrence of a most distressing internal hernia during the postoperative recovery, through this opening. We have warned particularly against this possibility in resections of the splenic flexure, since the entrance of the jejunum through the mesenteric root tends in these lesions to be more toward the left side than the right.

In resections of the right colon it is also desirable to have a long loop of ileum attached to the transverse colon, as shown in figure 2*b*, since it is important in order to restore the fecal stream that the spur or septum in the double barreled Mikulicz loop can be cut down for a long distance. This insures an adequate pathway for the feces to pass through the Mikulicz region.

Fig. 3—*a* amount of ileum, ascending colon, hepatic flexure and transverse colon shown in shaded lines together with the wide extent of mesenteric apron with regional ileitis which can be removed radically either in carcinoma or in regional ileitis. *b* demonstrates the devascularized segment of ileum for decompressing the ileum and a rubber clamp placed on it while a catheter or rubber tube is sutured in the end to be conducted to a bottle at the side of the bed for immediate decompression.

We have deliberately evolved and adhered to this modified Mikulicz type of procedure because in our hands it has given such satisfactory results. With it it is possible, by the staggering of the devascularized terminal loop of ileum, which one of us (F. H. L.)

first described and illustrated in figure 3b, to insert a catheter or a Paul tube into the end of the ileum immediately at the time of operation connect it by a rubber tube to a bottle beside the bed and accomplish immediate decompression of the small intestine. There is nothing more important, we believe, in any intestinal

Fig. 4—Involvement in regional ileitis of all the walls of the ileum

resection than the ability to decompress at the time the resection is done. Patients sometimes die following colon resections not because of the resection itself necessarily but as the result of the temporary obstruction which goes with it and the effect of this on their general condition and the suture line. It is to be noted in figure 3b that the loop of ileum into which the tube is inserted has been devascularized and will slough off even with the abdominal wall, thus resulting in a double barreled intestinal loop, the ends of which are at the same level on the abdominal wall.

The clamp on the spur of the Mikulicz loop is applied on the sixth to the seventh day, and it has been our experience that it is better to apply the clamp two or three times than to attempt to cut the septum of the spur with one long clamp. We fear the danger with the long clamp of including too much in the bite of the clamp and we believe that the hazard of perforation with such a long clamp is greater than with two or three small bites.

Of all the patients with carcinomas of the large intestine having resections in this clinic followed over five years, 43 per cent of those with carcinoma of the rectum and 57 per cent of those with carcinoma of the colon on whom the radical operation has been done have remained alive and well over that period of time without recurrence. The nonrecurrence rate in the carcinomas of the right colon have averaged at the same rate as have the carcinomas of the colon at other levels.

REGIONAL ILLITIS

The other condition which we wish to discuss is that of regional ileitis. There is little to be said concerning the cause of regional ileitis except that any lesion of obvious inflammatory character, which on microscopic examination demonstrates itself as inflammatory in nature by the round cell infiltration which is associated with it, and which involves, as does regional ileitis, all the coats of the bowel (fig. 4) must be assumed to be inflammatory even though the infecting agent cannot be demonstrated. It seems reasonable,

therefore, to conclude that regional or terminal ileitis is an inflammatory reaction to an agent not microscopically demonstrable. In all of these reported cases the lesion has been limited to the terminal ileum. It has been quite consistent in character, in symptoms and in appearance, varying only for practical purposes in relation to the complications associated with it, largely the result of perforations or mechanical obstructions, perforations which have produced local abscesses or sinuses by perforating into adjacent viscera.

The diagnosis has been based on the history of right lower quadrant pain, not infrequently diarrhea, and intermittent obstruction associated with it, chronicity of the history, weight loss and not infrequently a previous operation such as appendectomy, without relief. Palpable masses have occasionally been present and external and internal fistulas have been demonstrable in 25 per cent of the cases, so that whenever a patient comes to us with a history of having been operated on for appendicitis, followed by a chronic fistula, particularly when associated with intermittent obstructive symptoms, we are extremely suspicious of regional or terminal ileitis.

It has been possible in a large percentage of the cases to demonstrate the rigid ileum, as shown in figure 5, and in many others the typical "string sign" described by Dr. Burrill Crohn, as illustrated in figure 6.

The discussion of the treatment of regional ileitis is concerned with (1) whether it is to be treated expectantly and if so what can be done, (2) whether it is to be treated surgically in a conservative manner by lateral anastomoses as has been advocated by some, or (3) whether it is to be treated by a radical removal of the involved ileum and adjacent colon as we have employed, and what the results have been.

We know of no medical measures which can be applied to this disease that offer any prospect of limiting its extension. Not only is this true, but while one applies medical measures it is possible for the process

Fig. 5—Gross specimen of regional ileitis removed, showing extension to the ileocecal valve the infiltration of all the coats and stricturing near the ileocecal valve.

to involve adjacent structures, such as the sigmoid, to perforate into these adjacent structures and form sinuses into the sigmoid, bladder, vagina and externally as had already undeservedly occurred in many of these cases when sent to us for operation.

We have deliberately applied radical resection of the ileum, ascending colon and hepatic flexure to regional

ileitis because we believe that by this method we can most effectively remove the infected segment of bowel and with it the infected glands in its attached mesentery. We have been impressed with the desirability of continuing this radical plan of treatment in this lesion because there has been but one death in the 53 resections and that in the presence of an abscess and perforation, but particularly because in spite of such radical resections, there have been but 2 cases in which the disease has recurred in the remaining ileum. These recurrences took place in the beginning of our experience when we did removals of the ileum but with limited resections of the ascending colon, thus leaving infected glands in the remaining areas of attached mesentery. Since we have done more of these operations we have realized that the infecting process not infrequently extends over onto the ascending colon for varying distances, so that it is desirable to resect not only

Fig 6—Typical string sign of Crohn in regional ileitis. Note also in this the extension of the process onto the colon.

a long segment of ileum but also all of the ascending colon and hepatic flexure together with its mesentery. Since these wider resections have been done there have been no recurrences.

As is shown in figure 3a, one of the advantages of such an extensive resection of the terminal ileum and entire right colon with the right section of the transverse colon is the fact that with such an extensive resection a wide area of mesentery with its infected glands can be removed in this region. We have been impressed with the possibility that, if limited sections of ileum and colon are removed, one often leaves behind large, obviously infected and inflamed mesenteric glands probably harboring whatever the infecting agent is, and at least promoting the possibility of further infection of the remaining segments of bowel.

The same plan of resection of the right colon has been consistently applied in regional ileitis as has been applied in carcinoma of the right colon, that is, the modified Mikulicz plan of resection with secondary closure and with the devascularized segment of ileum

serving as a spigot for immediate decompression. This operation lends itself just as satisfactorily to all resections of the right colon as presented in this group of cases as it does to carcinoma of the right colon.

As a result of this experience, we have set up for ourselves certain rules to apply in cases of regional ileitis. One is that there is definitely a stage with red, acutely inflamed ileum covered with fibrin in which we would prefer not to resect. It is at this stage that the peritonium has not yet vaccinated itself well to the infection. It is at this stage that the inflammatory reaction within the mesenteric glands is acute and so makes them more difficult and less desirable to handle. Fortunately, it is at this stage so often that the patient has been operated on before coming to us under the mistaken diagnosis of acute appendicitis and nothing more than the appendix has been removed. This has been true in 25 per cent of the cases in which we have operated. This is fortunate, as it permits the patients to have vaccinated their peritoneal cavity well to the lesion and the lesion to have become less acute and more of chronic character. We have assumed the position that if these patients are to be operated on it is desirable when possible, as has usually proved to be the case, to remove radically all the segment of infected bowel together with this adjacent mesentery and infected mesenteric glands, as shown in figure 1a. We have realized the possibility of other segments of bowel being involved and have always insisted that the other levels of small intestine be investigated to make sure that other segmentally involved areas do not exist.

In any discussion of resections of the right colon by the employment of the plan of modified Mikulicz resection, it seems wise to discuss briefly some of the points particularly related to the successful second stage closure of the Mikulicz enterostomy after the spur has been cut.

We were interested in the beginning of our experience with this operation to have these patients back for closure of their temporary external ileocolostomy as early as possible, since they were never happy as long as even part of their feces was discharged through the temporary external ileocolostomy. In addition to this, many of those patients have had varying degrees of skin irritation about their temporary external ileocolostomies. We have become more and more convinced with the widening experience with the secondary closure of Mikulicz external ileocolostomies that it is wise not to attempt to close them earlier than two months after operation. If one attempts closure before this time the wound is often still edematous, there are small fluid pockets of undigested output in it and the peritoneum has not become firmly fixed to the neck of the intestinal spur. We have therefore taken the position that all these patients shall wait for two months before returning for their second stage closure. At the beginning of our experience we were often hesitant to do these secondary closures when there was considerable skin irritation about the external ileocolostomy of a right colon Mikulicz resection. We have now learned that no matter how much skin reaction there is they can be closed quite safely and that, since this reaction is largely of chemical or digestive nature, as soon as the ileocolostomy is closed it will disappear and promptly heal. We have learned that there is in all probability a high degree of local immunity in the tissues and that infection of these wounds rarely takes place even when

the closure is made in the presence of this skin irritation. There have been only three mild infections in all these resections.

When a patient returns at the end of two months for the closure of his external ileocolostomy we have also learned from this experience that one must be careful to investigate how low the spur in the double barrelled Mikulicz tube of bowel has been cut at the first

Fig 7—*a* inadequate cutting of the septum in the spur. *b* Note when the end of the Mikulicz enterostomy is closed and inverted and the septum inadequately cut how feces are thrown up against the closed end to threaten its reopening and also how inadequate is the aperture for the passage of the fecal stream. At *c* the spur has been well cut down. Note the adequate aperture for the passage of feces when the end of the Mikulicz enterostomy has been closed at the second stage. Note also as shown in *d* that this spur has been closed beneath the level of the fascia, contrary to the closure above the level of the fascia beneath the skin and fat. *d* is similar to *c* showing an adequate cutting of the spur with an adequate aperture for the fecal stream but in it is to be noted in a fat patient that the end of the Mikulicz enterostomy can be closed above the layer of the fascia being covered only by subcutaneous fat and skin.

operation. One may apply an Ochsner clamp on the spur at the first operation three or four times and cut the spur low, but as a result of the organization of the exudate in the spur, when the patient returns for the second stage the septum can frequently be still too high (fig 7 *a* and *b*). It is therefore very desirable that no patients have their external ileocolostomy closed as the second stage of the Mikulicz procedure until the septum has been demonstrated as absent or is cut down again by the application of clamps for a sufficient depth (fig 7 *c* and *d*). Unless this is done there will frequently be left a segment of uncut septum which, when the external Mikulicz has been closed, will throw the feces up against the closed end of bowel and threaten the establishment of a fistula (fig 7 *b*). There are two very important things in the second stage closure of a Mikulicz operation. One is that the septum has been cut low enough, and the second is that as the tube of bowel is prepared for closure at the second operation all indurated tabs of epiploic appendices or attached mesentery be freed from the bowel. The bowel must be dissected from the skin, the attached cuff of skin must be cut away and the bowel must be so freed from subcutaneous fat and so freed of its indurated fat pads of mesentery that when it is inverted by the

in, out and over stitch it will bury and invert itself as accurately as will a segment of free and unoperated on bowel within the abdominal cavity. We feel very sure that the complaints that are frequently made to us by surgeons visiting the clinic that they close the external ileocolostomy of a second stage Mikulicz operation satisfactorily but that at the end of a week or ten days it reopens are due to lack of attention to these details because of the fact that they have not completely freed the loop of bowel of all of its indurated mesentery and fat pads so that its walls can be easily inverted. It has been forced inward in spite of attached indurated pads of fat by the in, out and over stitch of catgut, and, as soon as the catgut has absorbed, the mucosa everts and a mucous lined, external fistula is again established. The principle of the successful closure of the external ileocolostomy of a second stage Mikulicz operation is involved in so freeing the external section of bowel that it can be accurately inverted without tension with three layers of sutures.

When we first began to close second stage Mikulicz operations we felt that the external tube of bowel now the common ileum and transverse colon with the spur cut had to be separated from skin, subcutaneous fat, fascia and muscle, leaving it attached only by the peritoneum. This is desirable, and it is desirable to invert the external tube of bowel so that it is below the level of fascia (fig 7 *c*). In patients with fat abdomens, however, this has not been necessary. It has frequently been satisfactory, as shown by Dr Cattell in this clinic, in such cases to separate the bowel down to the fascia, to bury it at the level of the fascia and then to close the skin and subcutaneous fat over it (fig 7 *d*).

As shown in figure 8, a small strip of rubber dam is left to emerge at the upper and lower angles of the wound and withdrawn on the fifth or sixth day. In no case has there been serious infection of the wound. In a few cases temporary fistulas have resulted, but it is rare in secondary closure of these Mikulicz procedures for the wound not to heal by first intention.

There have been nineteen deaths in the entire series of carcinoma of the colon and one in the resections for regional ileitis, most of which have occurred in the complicated resections, a mortality rate of 11.7 per cent.

In the discussion of this subject and our preference for the modified Mikulicz type of resection we do not wish to imply that it is the only type of operative procedure to be employed. We believe that every one must make his own decision concerning the type of operation he employs. We wish only to say that the employment of the modified Mikulicz type of operation for resections of the colon has given all of us a very high degree of satisfaction, that in our hands with its permitting immediate decompression, it allows us to do resections on patients with moderate degrees of obstruction in which we would otherwise do preliminary decompressions, and that with it has been eliminated largely from our minds the fear of leakage and the development of peritonitis.

Fig 8—A rubber dam brought out through the upper and lower end of the wound in patients after the Mikulicz enterostomy has been closed.

RESECTION AND IMMEDIATE ASEPTIC ANASTOMOSIS FOR CARCINOMA OF THE COLON

HARVEY B. STONE, M.D.
AND
SAMUEL McLANAHAN, M.D.
BALTIMORE

Surgical attack is at present the accepted method of treatment for cancer of the colon, although one is occasionally surprised to hear grave doubts expressed concerning its value. The doubts, however, do not exist in the minds of those most experienced in the field. Far from ideal though it is, such surgery does offer a very considerable chance of recovery from a condition that otherwise is admittedly hopeless. Those who have enjoyed extensive experience in this type of surgery agree on certain generally accepted principles. For instance, the necessity for preliminary treatment before operation and for careful postoperative handling is well known. Also important, in cases first seen in the phase of obstruction, is the directing of efforts at combating the obstruction before attacking the tumor itself. There are, however, a number of unsettled issues and it is with these that we propose to deal in this paper. They may be stated thus:

1. Is it better to attempt removal of the lesion immediately in nonobstructed cases or should stage operations embodying some form of preliminary drainage of the proximal bowel be employed?

2. When the growth is removed, should one try to complete the reconstruction of the alimentary tract at once or leave this for a subsequent procedure?

3. Should the technic of aseptic anastomosis be emphasized or is this of little importance?

We acknowledge as the first and basic principle that no hard and fast rules should be followed, each case being dealt with on its own merits and several alternative methods being given consideration. But however flexible the attack, there are reasons for preferring one alternative to another, and we think it is desirable to discuss these reasons.

We may state our own thesis thus: Unless specific objections present themselves, the ideal treatment of cancer of the colon is immediate primary resection of the lesion, along with a sufficiently adequate portion of bowel and the tributary lymphatic vessels and nodes, this to be followed at once by repair of the alimentary tract by means of a technic of the so-called aseptic type.

This thesis is by no means new, indeed it is as old as colon surgery itself. With the exception of the aseptic technic, it was the first method employed in removing growths situated in the colon. Johannes Mikulicz,¹ however, became dissatisfied with the procedure of resection and immediate anastomosis because of the high mortality rate from peritonitis. Following the lead of Bloch² and of Paul,³ who in turn, as Gibbon and Hodge⁴ point out, had been preceded by Bryant

and by Barton, Mikulicz in 1903 adopted the exteriorization method and thereby gave emphasis to a new and different principle, which through the next quarter of a century was to be widely heralded and generally employed. In discussing this principle of exteriorization, Rankin⁵ has recently referred to it as "probably the greatest single technical factor in advancing colonic surgery." He goes on to point out, however, that it has definite limitations as well as indications and that these have been generally recognized by the modern operator. During the past fifteen years many voices of authority have been heard to champion one or the other principle as applied in the resection of colonic carcinomas. Safety, through the avoidance of the possibility of leakage from an intraperitoneal anastomosis, has been the continuous and urgent appeal of the exteriorization principle. Safety, through the development of new technical methods of intraperitoneal anastomosis, thereby avoiding the many disadvantages of exteriorization, has been the constant goal of those who have developed the modern version of resection and immediate anastomosis.

Halsted⁶ early became interested in the development of experimental methods for doing closed types of anastomosis and later invented a special knife to be introduced by rectum for the division of the diaphragm between the anastomosed ends. Parker and Kerr presented their basting stitch operation in 1908, and this method has been widely used since that time. Various types of clamp methods have been introduced since O'Hara⁷ presented his instrument in 1901. Among these is the method we have used for more than five years which has been described by Owings and Stone.⁸

In addition to reasonably satisfactory methods of aseptic anastomosis, other factors have joined to contribute to the ease and safety of resection and immediate anastomosis. Among these are:

1. A better understanding and utilization of preoperative preparation.

2. Modern means of preventing or combating shock and maintaining an adequate fluid balance.

3. Better anesthesia.

4. The use of one or more of the sulfonamides in the prevention or therapeutics of complicating infections.

The group of 191 cases on which the accompanying statistics are based represents operations that we have performed over a twenty year period in six Baltimore hospitals. All the lesions were proximal to the rectum and if operable, could be removed by the abdominal route.

Operability rates have shown a general tendency to rise, yet great diversity is to be observed in studying various groups. Ochsner and DeBakey¹⁰ reviewed twenty-three reports and found that in fifteen of them there was an operability of 50 per cent or better while in the other eight reports the operability was less than

50 per cent. Cattell and Sugarbaker¹¹ in discussing the colon and rectum, report a rising operability rate from the Lacey Clinic, which was 58.3 per cent in 1929 and has risen to 84 per cent during the past two years. A serious study of operability is futile without knowing all of the many factors concerned, many of which are not apparent in individual reports. Conscientious operators try to increase their operability rates without having too great a concern for mortality. A decision prior to operation concerning the chance of removal of a given tumor is fraught with much uncertainty. Indeed, as we have stressed previously,¹² the decision may be difficult even at the time of operation and may require a careful, discreet beginning of resection to settle the matter. Our own operability rates based on the ratio of the number of tumors removed to the number of patients actually explored are shown in table 1. The rate for the entire group was 77.0 per cent.

Among the 44 patients with inoperable tumors 14 died, giving the high death rate of 31.8 per cent. The complications of perforation and obstruction served to place many of this group beyond the realm of surgical help. The problem of the management of the inoperable patient is a subject worthy of independent consideration.

Preliminary decompression by means of some type of colostomy, or by ileocolostomy in a right sided lesion, is axiomatic in a situation approaching acute obstruction. On the other hand, in the chronically obstructed colon which can be properly prepared by routine methods, and our experience teaches that most of them can, a preliminary drainage operation need only occasionally be used. There is much dissenting opinion on this point and many experienced surgeons advocate the routine employment of preliminary drainage especially for lesions on the left. While in no sense criticizing this practice we are convinced that it should be reserved for special indications, and it is our prediction that experienced operators will employ it less frequently in the future.

Rankin further suggests the advisability of a small concomitant proximal tube colostomy or enterostomy

TABLE 1—Carcinoma of Colon Operability Rate

	Cases	Resections	Operability
Right	37	33	89.1%
Transverse	30	25	83.3%
Left	124	89	71.7%
Total	191	147	77.0%

where distention and tension of the suture line are to be feared. This we believe to be sound in principle and agree that it is unnecessary as a routine measure.

In our own series of one hundred and four resections with immediate anastomosis of the aseptic type there were only nine instances in which the anastomosis was preceded by some type of preliminary colostomy. Two of these drainage operations were done elsewhere and the other seven were performed because of symptoms indicating an acute degree of obstruction. These 9

patients all survived the subsequent anastomosis. In 29 cases of resection and immediate anastomosis of the open type, only three times was preliminary external drainage utilized.

There was a variety of procedures employed in this series in addition to immediate resection followed by aseptic anastomosis. These were exteriorization according to the "obstructive resection" of Rankin with subsequent closure of the colostomy, an open type of anastomosis immediately following resection and an open type of anastomosis between the sigmoid and a

TABLE 2—Carcinoma of Colon Mortality of Resections Followed by Anastomoses of the Aseptic Type

	Resections	Deaths	Mortality
Right	16	3	18.7%
Transverse	16	1	6.3%
Left	72	7	9.7%
Total	104	11	10.6%

short rectal stump performed after an interval of from two to eleven months from the time of resection. During the latter period, bowel function depended on a temporary sigmoid colostomy. In addition there were 3 cases in which a permanent colostomy remained after the resection of a very low growth.

In the selection of operation, great stress has been laid repeatedly on anatomic and physiologic differences between the two sides of the colon. These differences in turn have led to the general conclusion that primary anastomosis is feasible on the right but dangerous on the left. Our experience reveals, on the other hand that, when obstruction is not present on the left, there is no great difference between the two sides from the standpoint of resection and immediate anastomosis. It is therefore our contention that one may as safely undertake the procedure on the left as on the right. Indeed, table 2, showing our mortality rates for resection accompanied by aseptic anastomosis, indicates a rate for the left side which is almost one half of that on the right.

Especially on the right side is exteriorization to be avoided because of the physiologic and psychologic complications attendant on ileostomy. The principle so often followed, and recently well rationalized by Fallis,¹³ of removing all intestine from and including the terminal ileum to a point well along on the right side of the transverse colon is sound. The types of union may be end to end, side to side or end to side, and these may be carried out by the open or the aseptic method. Because of the frequent discrepancy between the caliber of the ileum and the ascending or transverse colon operators have often resorted to side to side anastomosis. In this group of sixteen aseptic unions on the right it was possible to perform end to end anastomosis fourteen times with, however, three deaths. The ten open anastomoses were with one exception side to side and accounted for one death.

Uncomplicated lesions of the transverse colon lend themselves well to all of the several principles of treatment. Mayo and Simpson¹⁴ showed that extraperitoneal resection in this area had produced a mortality of

20 per cent in 95 cases, whereas the group of thirty-six segmental resections with primary anastomosis had yielded an operative mortality of only 11 per cent. They did not, however, state the type of union performed. Our small group of 16 cases carried out in one stage with an aseptic type of anastomosis showed only one death, or a rate of 6.3 per cent. The splenic flexure represents a portion of the colon distally placed from the

origin of its blood supply. It depends on terminal ramifications of the left branch of the middle colic artery and of the ascending branch of the left colic artery. For this reason a wide excision of intestine is important in order that one may bring the points of resection nearer the source of the blood supply. This may entail the removal of a large part of the colon on the left side with a subsequent anastomosis between the transverse colon and the sigmoid. We have on occasion extra-peritonealized the anastomosis as an added measure of safety. In performing any end to end union in the colon, one must ever be mindful of Lockhart-Mumery's classic lesson with regard to blood supply. He taught that clamps should be applied at an angle so that a greater portion of the antimesenteric border would be removed, thus assuring adequate blood supply to the cut margins of the bowel.

The left side of the colon has offered the greatest opportunity for employment of the ideal procedure. And indeed this procedure has in our opinion permitted the radical removal of wide areas of mesentery. This has been proved so important by the brilliant and painstaking pathologic studies of David and Gilchrist,¹⁵ and of Collier, Kay and MacIntyre¹⁶ and others. In 72 cases in which it was possible to perform aseptic anastomosis immediately following resection the mortality rate was 9.7 per cent. Many of these lesions lay deep in the pelvis and presented difficult technical problems. In nineteen left sided lesions an open type of anastomosis following the resection resulted in five deaths, a mortality rate of 26.3 per cent. Three of these deaths were attributable to an unsuccessful "tube anastomosis" whereby the proximal sigmoid end was invaginated into a short rectal stump by means of an attached rectal tube. It soon became apparent that no anastomosis should be immediately performed at this low level unless an aseptic one could be comfortably carried out. This was further attested by the happy outcome in four instances in which a temporary terminal colostomy was performed and where this same colostomy loop at a later stage was safely implanted into the short rectal stump by the same type of "tube anastomosis."

In the earlier cases of this group aseptic anastomosis according to the Parker-Kerr technic was the practice, while in the latter half of the time some form of clamp anastomosis has been employed. Special attention should be directed to the appendices epiploicae in preparing the intestine for suturing. These troublesome tags should be carefully dissected away before the bowel is ready for crushing. Following completion of the anastomosis it must be carefully tested with the finger for patency, because in more than one instance we have inadvertently caught the opposing wall with sutures and have had to take measures to release them. A rectal tube passed up through a sigmoid anastomosis and allowed to remain in place is a valuable measure.

The Miller-Abbott tube has been reported as of great benefit in giving a concomitant decompression in right sided lesions and in the treatment of postoperative distention. We have found it useful in the latter complication on a number of occasions.

Our experiences with succinyl sulfathiazole in the reduction of the intestinal flora preoperatively have been limited and do not enable us to draw conclusions. However, the investigations of Poth¹⁷ and the results following the use of this drug in the wards of the Johns Hopkins Hospital are most convincing. The local use of sulfamidamide within the peritoneal cavity and in the wound is undoubtedly of great assistance in combating infection and has become largely a matter of routine. Rankin,¹⁸ in discussing aseptic anastomosis with his clamp, ventures the belief that modern chemotherapeutic agents may now justify one in doing an open anastomosis if that is deemed preferable. While this is undoubtedly true, it carries with it the implication of a temptation to let up a little on standards of technic, to which temptation the conscientious surgeon will not allow himself to succumb.

Allen,¹⁹ Gibbon and Hodge,¹ Rankin¹⁸ and many others have written much to emphasize the superiority

of aseptic anastomosis over open anastomosis. Again, it is the ideal type of union, which, however, may not always be employed. Our own experience with it not only in malignant disease but in other types of colonic disease requiring resection has convinced us of its ease of accomplishment and of its true worth in terms of end results. This series includes 104 cases in which

aseptic anastomoses were performed. The mortality rate was 10.6 per cent (table 3), while that for a smaller series of thirty-four open unions was 20.6 per cent.

In analyzing the deaths, infection and especially peritonitis stand out as the most frequent causes. Among the one hundred and forty-seven resections of all sorts there were nineteen deaths or a mortality rate of 12.9 per cent. Fourteen, or 73.6 per cent, of these nineteen were from causes directly related to the operative procedure, while the remaining five, or 26.4 per cent were due to causes indirectly related (table 4). Hence it is to be observed that in both types of anastomosis infection is the great cause of mortality.

Considering the smaller special group of 104 cases of resection and immediate aseptic anastomosis, the deaths are still predominantly associated with peritonitis. Of the eleven fatalities in this series, eight could be traced to a probable leak about the site of anastomosis, with a resulting peritonitis. Of the remaining three, two were due to embolism and one to pneumonia. These eight fatalities represent the vulnerable point of this method, and yet they are to be set against the hazards of peritonitis, multiple operations and multiple anesthetics inherent in other techniques. It is our firm belief that a still more careful selection of patients, a more carefully applied technique and the use of newer aids already suggested here will result in a steady reduction in mortality for those who judiciously employed this method.

CONCLUSIONS

1 The variety of clinical problems presented by carcinoma of the colon requires that the surgeon have available a number of technical methods of attack on this disease.

2 Where there is complete or nearly complete obstruction, relief of the obstruction is the primary objective. Where conservative medical treatment is adequate to prepare the patient properly and to deal with slight degrees of obstruction, primary colostomy is not essential.

3 The sooner the growth can be removed, the better chance there is to secure a definite cure, therefore, in nonobstructed cases resection of the disease is the first surgical objective.

4 If circumstances permit, immediate anastomosis averts the necessity for multiple anesthetics and operations. Therefore, under favorable conditions, resection should be followed by immediate anastomosis.

5 The avoidance of open contamination is an important feature of the technical handling of these cases. Therefore, an aseptic type of anastomosis is a desirable technical procedure.

6 The ideal type of operation, in view of the foregoing statements, may be formulated as immediate resection, immediate anastomosis and utilization of the aspects of the aseptic technique.

7 The material we present herewith provides evidence that in a reasonably large number of cases, with a reasonably high percentage of operability, this ideal procedure may be undertaken with a mortality which is within reasonable limits.

8 There is no intention to present this method as the only proper procedure, since many alternative surgical maneuvers may be advisable or necessary in a considerable number of cases.

ABSTRACT OF DISCUSSION

ON LAIERS OF DRs LAHEY AND SANDERSON AND
DRs STONE AND McLANAHAN

DR C W MAYO, Rochester, Minn. The substance of the paper by Drs Stone and McLanahan is that the combined details of preoperative preparation, anesthesia, operation by the aseptic technique and the postoperative care in selected cases have led to their accomplishing the operation in question with a reasonably low mortality. I agree with them on the advantage of the one stage resection in cases in which it should be performed from the standpoints of time that the malignant growth remains in the body and economy of time and money to the patient, but I disagree that "aseptic" anastomosis in resection of the colon for carcinoma is the answer for all surgeons as to the method of performing the one stage operation with a low mortality. In my defense of the open one stage colonic anastomosis, I must be pardoned for presenting personal experience with 83 cases of carcinoma of the right colon with a mortality rate of 8.4 per cent, counting deaths from all causes regardless of the time the patient spent in the hospital. Of the eighty-three operations, thirty-three were performed with end to end anastomosis between the ileum and the transverse colon, over rubber covered clamps, with an inner row of catgut and an outer row of silk sutures, with a mortality rate of 3 per cent, the one death being of a man 82 years old. In not one of the 83 cases was enterostomy performed in addition to resection. In the same period during which these eighty-three operations were performed, I performed but six multiple stage procedures in this portion of the bowel. In the transverse, descending or sigmoid colon, if the malignant lesion has not perforated the serosa and is not large, if it tends to grow into the lumen of the bowel and the liver and adjacent glands seem to be free of metastasis by palpation, and if the bowel is redundant enough so that one can get well away from the growth and anastomosis can be accomplished without tension, I would agree that a one stage resection of the left colon by the open or aseptic method, as determined by the skill and judgment of the individual surgeon, is in order. Such growths, however, are not as frequent in the left colon as those which in my opinion require more radical operations, although when the lesion is situated in the lower portion of the sigmoid my choice of procedure usually is a one stage combined abdominoperineal resection. When the growth is situated higher in the sigmoid or in the descending colon up to the splenic flexure, my most common selection is an extraperitoneal resection with temporary catheter colostomy next to the proximal clamp, of which operations I have performed one hundred and eighty-four, with a mortality rate of 5.4 per cent.

DR HENRY W CAVE, New York. Dr Lahey has discredited the timeworn theory that all growths on the right half of the colon always show cachexia and anemia and all growths on the left side of the colon almost always indicate an obstruction. Many people with colonic growths on the left side of the colon present pain in the right lower quadrant, many are operated on for acute appendicitis because the right colon is the most distensible part of the colon and is pain producing, especially the cecum, when it is distended. The modified Mikulicz procedure which Dr Lahey has depicted certainly removes radically all the lymph bearing structures, lymph channels and nodes. I have carried out this procedure in 6 cases. As low a mortality rate can be obtained, however, with other types of procedures, such as ileocolostomy, either in one or two stages. Dr Lahey's thought in presenting this has been predicated on his conviction that no matter how able the surgeon, no matter what exposure, no matter what type of suture material or the type of suture, there was always a risk of leakage at the suture line, and any type of exteriorization was safer. In 19 instances of right sided growths, I have in the last two years used the Miller-Abbott tube or colectomy for ulcerative colitis two or three days prior to operation in order to decompress the lower ileum and the right colon. This takes a strain off the suture line after operation and there is no two stage procedure necessary. An interesting experience occurred recently with 43 cases of ileitis in which sulfadiazine was used by Dr Thomas

Mackie and his group, and they feel encouraged about the treatment of this disease with that particular drug. In the majority of instances the ileotransverse colostomy is wise. In any type of growth in the left colon, if there is the slightest distention a cecostomy prior to or concomitant with the operation, with primary resection and immediate anastomosis and a paralysis of the sphincter ani muscle either by cutting or by forceful dilation, is the safest procedure for a left sided growth. However, in defense of the Mikulicz or the exteriorization type, that too has proved safe and successful, provided one cuts the splenophrenic colic ligament and dislocates the entire left colon, bringing out the growth and later cutting it off and cutting down the spur. Sulfasuxidine preoperatively will certainly cut down the bacterial flora. Paralysis or cutting of the sphincter ani muscle is another point I wish to stress, and also a suggestion given me by Leland McKittrick to put down a Miller-Abbott tube four or five days before attempting a right sided colectomy or a left colectomy or a total colectomy.

DR ARTHUR W. ALLEN, Boston. Dr Lahey has met the problem by the exteriorization method, Drs Stone and McLanahan by aseptic anastomosis, usually without decompression of the bowel. Dr Cave calls attention to the use of the Miller-Abbott tube with primary suture preliminary to resection. I have met the situation in a different manner, and that is by a two stage procedure, first a preliminary anastomosis between the ileum and transverse colon in the right colon lesions and a preliminary decompression by cecostomy for left colon lesions. I came to this conclusion because the results were so poor by other methods. In an analysis to determine why there was a high mortality in certain groups of our cases, there were only two important factors. One was the method and the other the experience of the surgeon. I found in an analysis of a total of 400 cases done in one stage that there was a mortality rate of just under 20 per cent, whereas in 253 cases done during the same interval of time and in cases that were not as good risks as those in which one stage procedures were employed there was a definite reduction in the mortality from 19.2 in one stage operations to 13 per cent with two stage resection. Therefore I have attempted to carry on with the two stage method in most cases. The type of anastomosis seemed to play a role in the mortality rate. In the Parker-Kerr basting stitch technic the mortality rate was 11.6 per cent in 86 consecutive cases, in all the other types there was a higher percentage of mortality in our hospital. In the two year interval 1939-1941, there was a different picture. Here we have the Parker-Kerr anastomosis applied by the staff members. The mortality rate of 63 per cent in this group of 79 cases has incidentally had the benefit of the Miller-Abbott tube and the sulfonamides. It is, however, a satisfactory record. My early mortality rate in one stage procedures was so high that I had to find a better solution. In my hands the two stage operation with primary aseptic anastomosis has resulted in a mortality rate that compares favorably with Dr Lahey's and Dr Stone's. In inflammatory lesions the anastomosis should not be made by the basting stitch technic. In 3 instances in the large and 1 in the small intestine, I have had a late stenosis develop at the suture line following resections for inflammatory lesions. These anastomoses should be made in some other manner, perhaps with a preliminary well defunctioned colon, then after a period of three months an open anastomosis is the method of choice.

DR FRANK H. LAHEY, Boston. Let's forget the old Mikulicz operation which left carcinomatous bowel out on the abdominal wall with the possibility of local implantations in the abdominal wound. Any modern Mikulicz operation should include removal of the lesion at the time one does it, with removal of the same amount of mesentery that can be taken out by a primary resection. No one can select the type of surgery to apply to these complicated cases except with a large experience, and with this will come a method which for him is suitable. One can standardize it only by doing it often, and with that will be established a method for that individual. There is no need to worry about multiple anesthetics, if one has a good anesthetist. Spinal anesthesia is the type we have used, and that presupposes a good anesthetist, otherwise one will have plenty of trouble whether

the anesthetics are multiple or single, just as one will if one has an expert surgeon. In splenic flexure carcinoma, do not forget that the mesentery of the splenic flexure at the root is very thin and delicate. When you get close to the jejunal fossa if you take out very much and try to sew it together, the first cough postoperatively will blow it apart and you then have an internal aperture for a hernia. It is therefore important to have a good cuff of mesenteric root where the jejunum becomes retroperitoneal. In 25 per cent of the cases of ileitis that we see, there are fistulas into the bladder, into the vagina, beside the rectum or into the sigmoid. These are the cases in which we like to do the resections in order to get rid of the inflammatory lesion and of fistulas. Never plant a Mikulicz enterostomy in the midline in the epigastrium. Why? You will remember if you recall a midline epigastric ventral hernia. What is the characteristic of it? It pulls apart. Why? Because of the insertion of the transversalis into the peritoneum. You can transpose and implant any Mikulicz enterostomy to the left side of the abdominal wall. If need be you can take out all the transverse colon and ascending colon, mobilize the splenic flexure, drop it, and the ileum will go well over to the left side. We have several problems such as this to deal with, such as a pericecal abscess from an inflammatory lesion about a malignant growth of the ascending colon which has been drained through the right side. Obviously, that is an impossible secondary wound into which to plant a Mikulicz enterostomy. You can make a counter incision on the left, resect the ascending and transverse colon and implant the Mikulicz enterostomy into the left rectus. Never fail to have a colostomy or ileostomy looked at on the night of operation to make sure it is viable. Investigation of any colostomy or ileostomy the night of the operation for viability is extremely important.

DR HARVEY B. STONE, Baltimore. I agree with Dr Lahey that, while technical details are important, each man has to work those out for himself. The basic plea of our paper was for a reassessment of the principles concerned in the attack on cancer of the large bowel. There are two elements concerned: first, the time element, second, the safety element. The sooner a malignant growth anywhere can be removed, the better the prospects of cure. Therefore, as it is possible, with safety the first objective should be the early removal of the disease to stop its progress. A subordinate element of the time factor concerns the expense, the delay, the additional hazard to the patient, of multiple operations. It is not of primary importance but is worthy of serious consideration. The only reason that any one would controvert the principle that the immediate objective of the attack on cancer of the bowel should be its prompt removal is that prompt removal may not be safe. The history of colon surgery explains clearly the processes through which surgical thought has gone. The first attempt was immediate removal of the growth. The serious mortality encountered forced an alteration of that principle. Then technical improvements developed which set aside much of the danger that the pioneers had encountered in their immediate attack on the growth. The Mikulicz principle, preparatory treatment, improvement in anesthesia, and all the things which have been mentioned in detail this morning have combined to lead us to feel that it is time for a reassessment of our basic views. Whether we cannot revert, with the advantage of all these improvements, again to the point of view that our primary principle of attack should be the immediate removal of the disease. We hope that the safety factor which originally made us defer the primary attack has now been met sufficiently to do this. In confirmation of that opinion, I should like to call attention to the figures cited by Dr Allen. His improved mortality figures in his last chart of aseptic resections with preliminary colostomy are almost identical with our mortality figures for aseptic colectomy without preliminary colostomy. I urge you to consider whether the factors of safety have not advanced to a stage in which it is reasonable to alter our views as to the necessity of delaying attack on the disease, and the whole purpose of this discussion is the successful and permanent removal of the disease. Our plea is that our technical approach now justifies the adoption of immediate removal of the cancer as the first objective of our attack.

GASTROINTESTINAL DISEASE AMONG
INDUSTRIAL WORKERS

HAMIL C. MCGEE, M.D., PH.D.

WINSTON, III

AND

J. D. CRIGER, M.D.

LULASKI, VA.

To those of us with a particular interest in the health of men in industry it is well known that illness and injury arising out of industrial occupation account for but a small part of industrial absenteeism. Experience in various types of industry has shown that somewhere between 8 and 15 days are lost from work because of ordinary sickness and injury for each day lost because of sickness and injury of occupational origin.¹ This fact is more impressive when it is recognized that when occupation is but a contributing factor to a disability (acute or otherwise) lost time from that disability is apt to be charged in the record to an occupational origin. During the past two decades much has been written, said and done to protect man from many hazards of his job. Those physicians, industrial leaders and legislative

case, it must be admitted, medical science has little or no effective prevention. It is our purpose in the present report to direct attention to the second greatest cause of absenteeism in the experience of a part of the chemical industry. Acute disorders and disease of the gastrointestinal tract as a group rank next to acute respiratory disease in severity and frequency in this experience. Other industries, as well as the armies of the United Nations, have reported disease of the gastrointestinal system to be a significant cause of illness.²

Fig 1—Cause of 40,942 days lost time (severity)

planners who have participated in the recognized progress in this direction should take pardonable pride in their accomplishments. If the occupational origin of absenteeism represents roughly but one tenth of the total working time lost, surely there is good reason to seek means of reduction in the economic waste represented by the other nine tenths. Americans are thinking, with an intensity hitherto unknown, in terms of the total manpower of the nation and the best utilization of that manpower. For possibly the first time in our national history we are finding an acute need for our reserves—a need for the full productive capacity of every man and woman.

It is axiomatic that sickness should be prevented when possible, thereby avoiding the necessity for treatment. The prevention of illness in industry is a concern of both management and labor, the industrial physician and the individual employee, public health organizations and private practitioners. It constitutes a challenging community and national problem.

Acute respiratory disease causes the greatest amount of industrial absenteeism.¹ For acute respiratory dis-

Fig 2—Cause of 5,402 absences (frequency)

OBSERVATIONS

During the year 1941 the medical department of the Hercules Powder Company directed particular attention to the nature of complaints referable to the digestive system. The absentee figures in the present report represent the predominantly male personnel of several plants, varying in average payroll size from less than 100 to more than 4,000 employees. Because of inherent limitations in obtaining accurate information regarding illness, particularly illness leading to absences of but one or two days' duration, certain individual plant reports were admittedly incomplete. For reasonable evaluation we believe that the figures presented here represent approximately 20 million man hours.

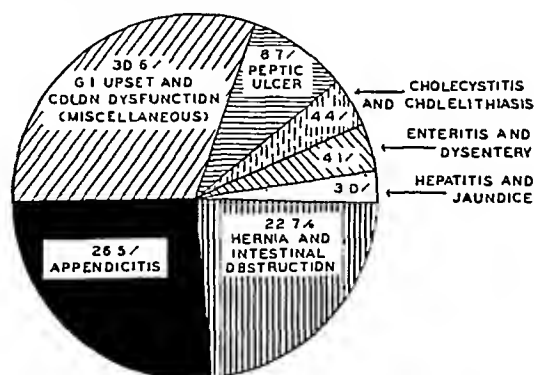

Fig 3—Cause of 7,605 days lost time from disease of digestive system (severity)

worked and are equivalent to the experience of an average payroll of 10,000 men for the calendar year of 1941. The occupations of the men varied from office work to outdoor construction labor. The one factor

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety Third Annual Session of the American Medical Association Atlantic City, N. J. June 10, 1942.

1. Piersol G. M. Role of the Physician in Industry in the Control of Acute Respiratory Diseases. J. A. M. A. 116: 1339-1342 (March 29) 1941.

2. Bashford Henry. Some Aspects of Sick Absence in Industry. J. Roy. San. Inst. 60: 360-363 (April) 1940. Day F. E. H. Gastrointestinal Diseases Among Steel Workers. Canad. Pub. Health J. 30: 550-557 (Nov.) 1939. Pepper O. H. P. Disease Expectancy in the New Army. War Med. 1: 463-469 (July) 1941. Hurst Arthur. Digestive Disorders in Soldiers. Am. J. Digest. Dis. 8: 321-323 (Sept.) 1941.

common to the occupation of these employees was that their jobs were directly concerned with the war effort of a chemical industry.

This group lost 40,943 days of their expected working hours from all causes, an average of 41 days per employee for the year. There were 34,018 days lost because of sickness and 6,925 days lost because of

Fig. 4—Cause of 1,292 absences due to disease of the digestive system (frequency)

accidental injury. Twenty-five per cent of all lost time in this group resulted from respiratory disease, 18.6 per cent from disease of the gastrointestinal system, 11.4 per cent from disease of the nervous system (the diagnoses of neurosis and psychosis were frequent in this group) and 5.6 per cent from degenerative disease (primarily of the cardiovascular system). The relative importance of the broad causes of absenteeism is shown for severity in figure 1, for frequency in figure 2.

Of the total of 7,605 days lost because of gastrointestinal disease, 79.8 per cent of the time lost was due to acute digestive upsets, dysfunction of the colon, acute appendicitis, hernia and intestinal obstruction (fig. 3). The designation gastrointestinal upset includes instances of irritable colon, the nausea of postalcoholic malaise and abdominal discomfort of uncertain origin. The relative importance of these gastrointestinal causes

of lost time from the point of view of frequency is shown in figure 4.

When the number of workmen with digestive complaints reporting to the plant physician is plotted against the days of the week, it is often found that such complaints occur with increased frequency on Monday. The composite experience of two plants during the past six months is presented in figure 5. It has been our observation that well known American habits of "relaxing" over the week end (excesses in food and alcohol and insufficient sleep) play a prominent role in the causation of Monday morning dyspepsias. Holidays have the same undesirable reputation with medical departments of plants. Figure 6

Fig. 5—Distribution through week of digestive complaints resulting in visit to medical unit (experience of two plants over six month period)

shows the influence of past Christmas and New Year diversions on the frequency of digestive complaints in two plants. This figure includes only those who reported for work and sought assistance at the plant medical quarters.

COMMENT

There is an increasing consciousness on the part of physicians and industrial management alike of the loss in production which results from sickness of industrial workers. The present acute demands on industrial output together with the increasing shortage of both skilled and unskilled personnel have thrown into glaring relief all types of worker absenteeism.

Physicians should be the first group to admit the influence of the unsolved medical problems of the lack of scientific knowledge of many acute diseases which afflict man during the most active and productive period of his life, on absenteeism. This important factor in loss of industrial production is one which must await further painstaking progress. An examination of this and other reports from medical departments in industry indicates, however, that lack of medical knowledge is by no means the entire problem. There is reason to believe that knowledge now available is not properly or completely utilized for its full value. Many absences due to disease or dysfunction of the gastrointestinal system are pre-

Fig. 6—Digestive complaints in relation to holidays

ventable. From our experience with digestive complaints in industry, we question whether we are using all opportunities to practice preventive medicine. The workman needs to replace erroneous ideas by factual and correct concepts for the care of his health. From our experience we feel that these workmen welcome and respond to, in an encouraging manner, the precepts of physicians who take time to explain useful health facts. The personnel of industry welcomes knowledge concerning the functions of the human body and the causative factors of ill health. The physician will do well to take time to supply useful medical information in the effort to counteract and replace much current misinformation. The past record of preventive medicine in this direction augurs well for increased effort along rational lines. This is an equal responsibility of the physician in private practice, the physician in public health service and the physician in industrial medicine. No one group alone can meet the challenge. The individual industrial worker can do much to increase his serviceability to himself, his family and his country. Voluntary abstinence in food and drink,

a more wholesome use of idle hours and a proper respect both for adequate sleep and for the inherent limitations of all human flesh will give men of industry large returns

ABSTRACT OF DISCUSSION

DR. FREDERICK H. SHULTZ, New York. The authors have brought out that gastrointestinal diseases are an important cause of nonoccupational absenteeism. I am sure that others can report experiences which substantiate these findings. In a group of 650 ground personnel serving transoceanic planes, we have tabulated all nonoccupational illnesses. Absenteeism of this kind has amounted to 2.25 days per man in a period of twelve months ended recently. Respiratory diseases have been the cause of 49.8 per cent of this lost time. Gastrointestinal complaints, the next most frequent single cause of disability account for 18.8 per cent. This latter figure of ours is close to the authors' figure of 18.6. Similarly, Monday is the most frequent day of the week for gastrointestinal upsets. A discrepancy between our figures of nonoccupational absenteeism is seen in the respiratory illnesses. The common cold infection of the sinuses, bronchitis and pneumonia account for about 50 per cent of our total and only 25 per cent of the authors'. This difference may be explained by the fact that they have drawn their averages from employees in a number of plants located in all parts of the country. Our figures, on the other hand, are drawn from a group in one temperate area with a winter season with changeable weather attended by a high incidence of upper respiratory infections in all classes and in all occupations.

DR. STANLEY H. OSBORN, Hartford, Conn. One interesting point brought out is absenteeism on Mondays and on December 26. There was also a great increase of absenteeism on January 5 and 6. I do not know what days those fell on. In several of the medical societies over the country during the last two or three months those who have been interested in war production have expressed the opinion that much can be done to increase war production by discussing this matter of the day of return to work with the staffs of hospitals and the state, county and city medical societies. This is necessary if we are going to put forth our full efforts in this war to check this tendency. Some physicians say to the patient, 'Oh, you will be all right to go back to work Monday' or again, 'It will be all right to go back on July 5'. It is a habit to mention some particular day, a day after a holiday or a Monday. This may not apply to this paper, for the authors have checked up carefully, apparently, but it is a point to bring out as one angle of absenteeism. It is vital not to disturb production by letting one or two men step out of the production line when they should be on the job. Anything we can do to encourage patients to remain at work when it is unnecessary to be absent anything we can do to urge patients to get back as soon as they can and not on 'Monday,' or 'after the holiday,' will help win this war.

DR. LEMUEL C. MCGEE, Wilmington, Del. I have no answer as to the cause of the slight increase in digestive complaints on January 5 and 6. There are undoubtedly other factors which we cannot evaluate now, because there are many variables. The two factors of holidays and week ends were outstanding and apparently could be evaluated regardless of other factors. The second item, that of the attitude of physicians in private practice who see these men, is significant. I suspect that when I was in private practice I was not aware, as I now am, of the carelessness with which I told a patient to remain away from work. I probably leaned over backward in my recommendations in the fear that something might happen to aggravate his illness or injury. In many instances the patient would have been better to go to work. The physician should take the time to inquire regarding the nature of the patient's industrial activity to determine accurately whether or not that activity would handicap him in his recovery. Many patients will recover more quickly by following their occupation than by remaining restive and away from work. We are trying to establish this idea without having physicians feel that we are interfering with the patients; that is, the employee's, personal welfare.

SYPHILIS AMONG MEN OF DRAFT AGE IN THE UNITED STATES

AN ANALYSIS OF 1,895,778 SEROLOGIC REPORTS OF MEN AGED 21-35 WHO WERE EXAMINED UNDER THE SELECTIVE TRAINING AND SERVICE ACT OF 1940

R. A. VONDERLEHR, M.D.

Assistant Surgeon General U. S. Public Health Service

AND

LIDA J. USILTON, M.A.

Principal Statistician, Division of Venereal Diseases
U. S. Public Health Service

WASHINGTON, D. C.

For years those struggling with the syphilis problem in the United States have been fighting an unknown antagonist. What is the problem? Where is it? Lack of satisfactory answers to these questions has handicapped every effort at syphilis control. The objective of this study is to discover, for the purpose of applying the machinery of control more efficiently, what and where the syphilis problem is.

SOURCE AND NATURE OF MATERIAL

The data used were taken from the reports of clinical examinations and blood tests given to 2,093,138 selectees and volunteers through Aug. 31, 1941. The Selective Training and Service Act of 1940 requires a routine serologic blood test for syphilis as a part of the general examination of every draftee and volunteer. The results of these tests were recorded in quadruplicate on standard report forms, together with a statement by the examining physician as to the presence of primary or secondary lesions. One copy of each form was forwarded to the United States Public Health Service by the health officers of forty-four states and the District of Columbia. Through April 15, 1941, 1,051,985 reports of blood tests had been received. Another 1,041,153 were received through Aug. 31, 1941. A summary of the first reports has been published.¹

The study does not include data from Idaho, Kentucky, Oregon and Vermont. These states did not use the standard report forms, and the data they supplied were incomplete. A further reduction in the number of cases included in the study was made when all men under 21 and over 35 were excluded. In most states their number was too small to yield rates which could be used with confidence. In addition, men of unknown age or residence were excluded because it was impossible to classify them properly. Finally, since races other than Negro and white were grouped with unknowns in the tabulations, they were excluded also. The study therefore deals with white and Negro men of known residence, aged 21 to 35 inclusive.

The proportion of the total sample lost because of the exclusions just described was small. Of the total 2,093,138 men for whom reports were received, 114,865 were excluded for age and another 82,495 for lack of data regarding race or residence. Thus, reports on 1,895,778 individuals, 90.6 per cent of the total number reported, form the basis for all calculations.

DEFINITION OF RATES

All rates represent the proportion of men between the ages of 21 and 35 with suggestive early lesions or with positive or doubtful serologic test results. "Observed" rates refer to the group actually examined.

"Corrected" rates are an estimate of the prevalence in the entire male population between the ages of 21 and 35

It might be objected that the inclusion of doubtful tests among the positives, by increasing the total number of infections would make the rate too high. However, in the 1941 evaluation of serodiagnostic tests for syphilis² less than 0.3 per cent of positive reactions

CORRECTION FACTORS

The chief factor which required correction in the rates was that of age. The younger men, for the most part without dependents or occupations to defer them from the draft, were numerically more strongly represented than the older men. This bias was constant throughout the sample and, since positive blood tests were found more and more frequently with increasing

were found in known nonsyphilitic bloods, whereas at least 10 to 15 per cent of known syphilitic bloods gave negative reactions. It is therefore highly probable that the total number of positive reports would be increased rather than decreased if an infallible criterion for the presence or absence of syphilis could be found and applied. This interpretation is, of course, valid for statistical purposes only. It might lead to tragic errors if applied to the diagnosis of individual cases.

² Parran, Thomas and others. Serodiagnostic Tests for Syphilis in State Laboratories. The 1941 Evaluation of Their Performance. J. A. M. A. 117: 1167 (Oct. 4) 1941.

age had the effect of lowering the rates. Consequently the correction for age raised the national rates in every case. Among the rates corrected for age only, i. e. the rates specific for race and residence, there is only one instance in which correction produced a reduction in rate. This was among rural Negroes in Kansas, where, probably because of the small number tested, a higher rate was found among the younger men. Similarly there was only one state in which the total rate for either whites or Negroes was lower after correction. In New Mexico the Negro rate was reduced from 318.8

to 3048. In this case too few rural Negroes were examined to provide corrected rates for the group.

The direction of the biases introduced by race and residence was less constant than were those resulting from age. In some states, particularly those with large Negro populations, proportionately more colored than white persons were tested, elsewhere the reverse was true. Similar variations with regard to urban and rural residence existed. The total effect of these variations was to increase the rates, mainly by inclusion of an undue proportion of Negroes, thus counterbalancing to some extent the lowering of the rates by the age distribution.

This is demonstrated in some states where certain corrected rates were appreciably lower than the observed rates. These include Florida (total rate), Georgia (total rate), Louisiana (urban rate), Maryland (rural rate) and Mississippi (urban rate). In each case in which correction resulted in reduction there was a smaller proportion of Negroes among the state population than among the individuals examined.

For the three factors age, race and residence the rates can be corrected to represent the prevalence of syphilis with reasonable accuracy as far as it is reflected in the occurrence of positive and doubtful serologic reactions and suggestive early lesions. But other less tangible factors of selection exist in the sample cannot be denied. A few that come most readily to mind are marital status, permanence of residence in a community and economic status. These cannot be identified with assurance, much less evaluated or corrected, and it must suffice that their existence is suspected but their effect unknown.

CALCULATION OF THE RATES

The methods of calculating the rates and of making the corrections were sufficiently simple and straightforward. The number of men examined and the num-

ber in whom evidence of syphilis was found were tabulated according to residence (rural or urban), race (white or Negro) and age. From these two sets of figures, specific rates of prevalence were calculated. These rates were then weighted by the state populations in corresponding age, race and residence groups. The populations used for weighting were obtained from the

1940 census reports. The census tabulations, however, set up the age limits as 20-24, 25-29, 30-34, whereas the selectee tabulations had the age limits 21-25, 26-30, 31-35. Consequently it was necessary to interpolate. This was done by means of the La Grange formula.

† Number tested insufficient for computation of rate.

applied to the cumulative population curves. Nine fixed points were used for this purpose (a polynomial of the eighth degree).

In some states the number of Negroes tested (urban, rural or both) was so small that no rates could be calculated. In all such cases the entire group was omitted from both numerator and denominator of subsequent calculations. In other instances race-residence groups contained so few individuals that only one or two of the age specific rates could be calculated. When this occurred the missing rate (or rates) was estimated on the basis of known rates for the other age groups.

The age specific rates were multiplied by the corresponding state populations to get the estimated total number of persons in each age-race-residence group showing some evidence of syphilis. When this estimated number of infected persons is divided by the state population of the group, the result is the rate corrected for age. The total estimated number of infected persons for the state in each race and residence group divided by the total populations of these groups gave the corrected rates for the state by race and resi-

dence The same process applied to the total number of syphilitic men and the total populations in the forty-four reporting states and the District of Columbia gave the corrected national rates by race and residence

HOW MUCH SYPHILIS?

Now, how much syphilis is there among white and Negro men in the United States between the ages of 21 and 35? The corrected rate of prevalence is 477 per thousand (table 1) Among the men actually examined and without any correction the rate is 453 per thousand (table 2) The highest rate of prevalence is among Negroes, the corrected rates for the entire country being 272.0 per thousand for Negroes and 23.5 per thousand for white men (table 1)

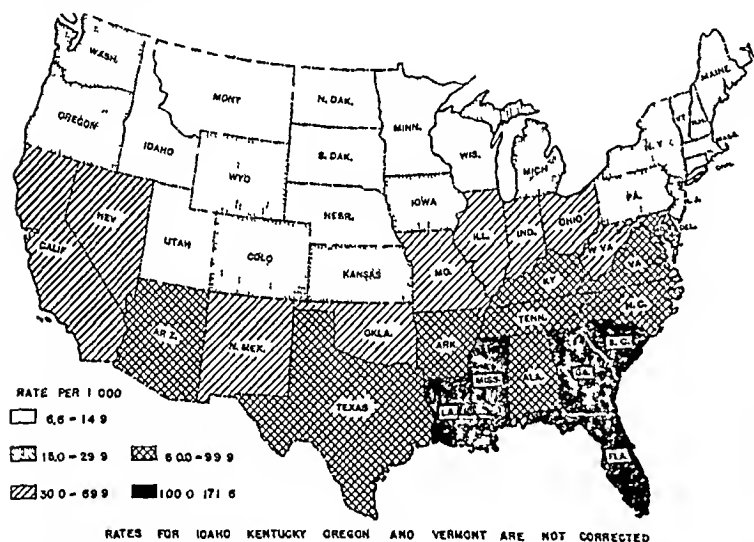

Among both white men and Negroes the rates rise sharply with increasing age Table 2 shows observed white and Negro rates for the three age groups in both urban and rural areas Among the white urban dwellers the rate of prevalence is almost four times as high in the age group 31-35 as in the age group 21-25 Among Negro urban dwellers the rate among the oldest

Negroes the rate is highest in Florida, Texas, Georgia, Maryland, Mississippi, Arkansas and New Mexico

In the states having Negro populations of any significant size the Negro rates are many times higher than the rates for white men And high Negro rates in general tend to be associated with high white rates This relationship, however, is not a constant proportion Indeed, in those localities where the Negro rates are highest the white rates are relatively much higher than in areas where the Negro rates are low Thus the high Florida Negro rate is only 7.6 times Florida's white rate, but the relatively low Negro rate in Massachusetts is 12.8 times the white rate The tendency applies as well to large areas as to individual states Table 1 shows that in the three census divisions having the highest prevalence of syphilis the Negro rates are less than ten times the white rates, whereas in the four divisions with the lowest prevalence the Negro rates are more than ten times the white rates

On the whole the highest rates are found in the Southern and agricultural states, the lowest in the Northern and industrial states As groups the New England states show the lowest rates, the East-South Central the highest

It has long been suspected that prevalence rates of syphilis were much higher in urban than in rural areas The selective data indicate that this supposition is only partially true (table 3) Both white and Negro rates for the country as a whole are higher in urban than in rural areas, but the total corrected rates in rural areas are 49.4 per thousand as compared with 46.5 for urban areas This may be explained by the fact that in the combined white and Negro total for all states there is a preponderance of Negroes in the rural areas Thus, combined white and Negro rates are higher in rural areas whereas white and Negro rates separately are higher in urban areas

Rates per thousand for two million selectees blood tested for syphilis corrected for age, race and residence within each state reports received November 1940 through August 1941

men is about twice the rate among the youngest men This, of course, does not mean that the older men are exposed to syphilis twice or four times as fast as the younger men but rather that there is a constantly accumulating backlog of uncured syphilis This is due in part to the fact that too much syphilis never is brought to treatment and in part to the fact that too many syphilitic patients are not held through an adequate treatment course

WHERE IS IT?

Of greatest practical value to those operating the control machinery is the distribution of syphilis Where is it? The rates by state and region given in table 1 are most effectively illustrated on the map showing total rates of syphilis in each state It will be seen that the highest rates are in Mississippi, Florida, South Carolina, Georgia and Louisiana When white and Negro populations are considered separately the same states generally show the highest prevalence rates for both groups The rate of prevalence among white men, for instance, is highest in New Mexico, Texas, Florida, Arizona, South Carolina and West Virginia Among

SUMMARY

1 The study is based on the serologic blood test reports received through Aug 31, 1941 of 1,895,778 white and Negro men between the ages of 21 and 35 tested under the provisions of the Selective Training and Service Act of 1940

2 The rate of prevalence based on positive and doubtful blood tests among the selectees examined is 453 per thousand The rate of prevalence for the entire male population of the United States between the ages of 21 and 35 is estimated to be 477 per thousand

3 The rate of prevalence among Negro selectees is 252.3 per thousand, among white selectees 17.4 per thousand The estimated rate of prevalence for the entire male Negro population aged 21 to 35 is 272 per thousand, for the entire male white population 23.5 per thousand

4 The rate of prevalence among selectees from rural areas is 43.8 per thousand, from urban areas 46.1 per thousand The estimated rate of prevalence among the entire male population aged 21-35 in rural areas is 49.4 per thousand, in urban areas 46.5 per thousand

5 Highest prevalence rates (white and Negro) are found in the Southeastern states, the lowest in the New England, West North Central and Middle Atlantic states

CONGENITAL AND ACQUIRED SYPHILIS
IN INFANTS AND CHILDRENTREATMENT WITH MASSIVE DOSES OF ARSENIC
INTRAVENOUSLYI MICHAEL LEVIN, MD

CHICAGO

The favorable implications of massive dose arsenotherapy of early syphilis in adults by the intravenous drip method focused our attention on the possibility of employing such a method in the treatment of congenital and acquired syphilis in infants and children.

The following report is presented to record the results of treatment of 36 infants and children, 32 of whom had congenital syphilis and 4 acquired syphilis, the study extending from August 1940 to the present date. We have attempted to evaluate the efficacy, optimal dosage, technique and toxicologic effects of five day intravenous drip mapharsen therapy.

The spirochætos of congenital syphilis with its widespread changes presents a far more complex problem than the early syphilis of adults. The nutritional and developmental status of the infant has been profoundly altered, growth and metabolism are retarded. Neonatal syphilis calls for, first, exacting pediatric care to save life and, second, antisyphilitic treatment.

PLAN OF STUDY

The status of the serologic reaction of the blood and of the liver, kidneys, bones and hemopoietic system was studied immediately before, during and after treatment. Preliminary laboratory studies included roentgenograms of the long bones, the standard and quantitative Kahn tests, the Kolmer complement fixation test, complete blood counts including a platelet count, urinalyses including a determination of urobilinogen excretion, and blood chemistry determinations including those of the nonprotein nitrogen, total serum protein, serum albumin and globulin, icteric index, calcium, phosphorus and ascorbic acid. During treatment blood counts and urinalyses were done.

On the day after the completion of the mapharsen venoclysis all laboratory determinations performed before treatment were repeated. During the remainder of the child's stay in the hospital quantitative Kahn tests were performed weekly and urinalyses, blood counts and blood chemistry determinations as indicated. Following discharge from the hospital all patients returned monthly to our outpatient clinic for further serologic study, clinical observation and infant and child welfare guidance. Roentgen studies were repeated every three months.

Read before the Section on Pediatrics at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

The Chicago Board of Health with Dr. Herman N. Bundesen as president assisted in the infant and child welfare. Dr. Ida Kraus Ragens made the blood chemistry determinations and the Cook County School of Nursing made the social service investigations.

From the Children's Division of the Cook County Hospital, the Cook County Graduate School of Medicine, the Department of Pediatrics of the University of Illinois College of Medicine and the Department of Public Health of the State of Illinois. Dr. Roland R. Cross, director. Dr. Herman M. Soloway, V.D. control officer and Dr. Howard Shaughnessy, director of laboratories.

TREATMENT

Preparatory—Before we proceeded with the institution of intravenous arsenotherapy the physical and nutritional status of the infant or child was carefully studied. Extremely debilitated infants observed in the neonatal period and those seen in the first half year of life with evident syphilis of the skin, viscera or bones were never placed on specific therapy until their ability to take food and maintain themselves was proved. During this period they were given a preliminary course of mercurialunctions (1 Gm. of 10 per cent ointment) three times a week for a period of two or more weeks, until they gave satisfactory evidence of a favorable response as shown by a gain in weight and improved clinical appearance. Infants with severe anemia were given citrated blood transfusions from our blood bank in the amount of 10 cc per pound of body weight. There was no restriction of diet during treatment.

Dosage—Our approach to the problem was with caution because our previous experience with the precarious physical condition of syphilitic infants had taught us that unexpected fatal response to arsenical therapy can occur. Although the Eastern investigators¹ did not vary the dosage of the drug according to the weight of the patient, we assumed a standard of a 150 pound (68 Kg.) adult receiving a daily total of 240 mg. of mapharsen, or 1.6 mg. per pound of body weight a day. This dosage we employed in our early cases (11 patients).

The absence of severe toxic reactions and our failure to obtain rapid serologic reversals prompted us to increase the daily dose per pound of body weight to 2 mg. (9 patients), 2.5 mg. (17 patients) and 3 mg. (3 patients). The total dose for five days was calculated and divided according to the following plan. On the first day of treatment 10 per cent of the total calculated dose was administered, on the second day 15 per cent of the total dose, and on the third, fourth and fifth days 25 per cent of the total dose. Graded dosage was used for the detection of possible toxic reactions.

Five per cent dextrose was selected as the diluent because the added carbohydrate was a source of food and glycogen storage for protection of the liver. The amount of solution used in infants was 30 to 60 cc per pound of body weight a day, regulated to flow for a period of ten hours. For infants the amount of solution averaged between 300 cc and 600 cc a day, for older children a maximum of 1,000 cc was used.

Technic—In infants the site of election for venoclysis was the internal malleolar vein exposed by cut-down. A cannula, gage 18 or 20, was tied into the vein to allow proximal flow. At the end of each day's treatment the vacoliter type tube was disconnected, an obturator inserted into the cannula and a sterile dressing applied. Obstruction to renewed venoclysis on succeeding days was encountered infrequently, whereupon a fresh cut-down was carried out on the opposite extremity. In older children needles of a similar gage were inserted for proximal flow into the veins of the forearm, usually on the anterior or outer aspect, between the elbow and the wrist if pos-

sible. Otherwise the cubital veins were used and alternate arms on succeeding days.

Types of Cases—Our material consisted of two groups of cases: (1) 32 children with congenital syphilis, 18 of whom were under 6 months of age, and 14 between the ages of 6 months and 6 years; (2) 4 children with acquired syphilis in the primary or secondary stages. There were 17 white children (11 boys and 6 girls) and 19 Negroes (11 boys and 8 girls). Three patients were accepted for treatment who had previously received inadequate acetarsone therapy. We would have preferred to treat only patients with congenital syphilis under 6 months of age.

At the beginning of this study we were concerned first with the development of a satisfactory technic for prolonged venoclysis and second with the determination of the toxic reactions of massive intravenous arsenical therapy. Hence we accepted a variety of patients in order to familiarize ourselves with the drug and the technic.

reversal was obtained in 6, or 50 per cent (table 2). This was in sharp contrast with the 100 per cent serologic reversal in the group with acquired syphilis.

In the group of 7 children between 4 and 7 months of age there was 1 serologic reversal (table 3). However, in 2 others there was a decreasing titer of the quantitative Kahn test to doubtful, which may be of significance. Four of these infants were given a second course of treatment because of a rising titer at the end of six months. They show falling titers, distinctly lower than after the first course of treatment.

Of the remaining 13 children, ranging in age from 1 to 6 years, there was serologic reversal in 5 and a decreasing titer of the quantitative Kahn test in 8 (table 4).

Toxic Manifestations—Toxic reactions of a minor degree were frequent. However, it was not necessary to discontinue treatment in any instance.

RESULTS

Clinical and Serologic—The 4 children with acquired syphilis, 1 with chancre of the lip and secondary lesions and the other 3 with anal condylomas and mucous patches, showed a prompt disappearance of spirochetes within forty-eight hours and a clearing of lesions five to seven days after treatment. Serologic reversal was obtained in all 4 cases (table 1), 2 in four months, 1 in five months and 1 in eight months. This has persisted to the present time, from ten to eighteen months after the reaction became negative; spinal fluid examinations in all 4 cases showed no abnormalities. In the absence of clinical and serologic evidence of syphilis we are classifying these as presumptive cures, a result which we anticipated from statistics given on adults treated early.

The remaining 32 patients all had congenital syphilis and, as was expected, response to treatment was variable and not nearly as dramatic as in the group of children with early acquired infection. Decided improvement in general appearance and uniform weight gains were evident within one month after the onset of treatment of the infants with congenital syphilis. Of the 12 babies under 3 months of age serologic

reversal was obtained in 6, or 50 per cent (table 2). This was in sharp contrast with the 100 per cent serologic reversal in the group with acquired syphilis. In the group of 7 children between 4 and 7 months of age there was 1 serologic reversal (table 3). However, in 2 others there was a decreasing titer of the quantitative Kahn test to doubtful, which may be of significance. Four of these infants were given a second course of treatment because of a rising titer at the end of six months. They show falling titers, distinctly lower than after the first course of treatment. Of the remaining 13 children, ranging in age from 1 to 6 years, there was serologic reversal in 5 and a decreasing titer of the quantitative Kahn test in 8 (table 4).

Toxic Manifestations—Toxic reactions of a minor degree were frequent. However, it was not necessary to discontinue treatment in any instance. Fever occurred in 29 of 40 treated patients. The temperature rose almost invariably toward the end of the day's treatment, persisted for four to eight hours and was always normal the following morning. In 10 cases the fever was first noted on the first day, in 5 on the second, in 6 on the third, in 4 on the fourth and in 4 on the fifth day. The elevation was observed during one day in 7 instances, during two days in 12, during three days in 4, during four days in 3 and during five days in 2. Mild pyrexia was present in 3 children for one to three days following cessation of treatment.

Local reactions were observed in 5 instances, urticaria in 2 and erythema in 3. The eruptions usually occurred on the first day of treatment and disappeared within two days. There was an associated mild elevation of temperature. Neither secondary toxicodermia nor exfoliative dermatitis was observed. Vomiting was present in 8 of the 40 cases under treatment and abdominal distention in 3. Irritability was noted in 5 children, headache in 2 and listlessness in 1. Localized phlebitis was recorded in 7 instances with local abscess formation in 1.

Laboratory Studies—There was no significant alteration in the red count, white count or hemoglobin level. No instance of anemia, granulocytopenia or thrombopenia of sufficient severity to interrupt treatment was observed, nor were there any striking changes noted in the period following treatment.

Variation in the icteric index levels was negligible. There was no evidence of clinically recognizable jaundice.

Blood chemistry studies of nonprotein nitrogen, total protein, serum albumin and globulin, calcium and phosphorus revealed only insignificant changes.

Blood ascorbic acid levels were studied in 28 cases before and after treatment. In 21, the values were subnormal preceding therapy, further depression occurring in 17 following treatment.

tain themselves before being subjected to massive intravenous arsenotherapy.

Careful laboratory and roentgen studies before, during and after treatment were carried out. Varying dosages of mapharsen were employed.

There were no serious toxic reactions and there was no mortality.

The 4 patients with acquired syphilis showed serologic reversal within four to eight months, negativity persisting for ten to eighteen months thus far.

Of the 32 patients with congenital syphilis (12 under 3½ months of age), 12 showed serologic reversal, a presumptive favorable result in 37.5 per cent.

We believe that a rising titer of the quantitative Kahn test six months after treatment probably indicates failure and that a second course of therapy should be given.

Total number with serologic reversal, 2

Daily urinalyses during treatment revealed no evidence of kidney damage, and subsequent examinations corroborated this.

There was no significant alteration in the urobilinogen excretion in the urine as a result of treatment.

Roentgenograms revealed in general definite evidence of bone healing following arsenotherapy. Further analysis of the roentgen studies, including the possible correlation with blood calcium, phosphorus, phosphatase and ascorbic acid determinations, as well as the serologic reaction, will be published at a future date.

SUMMARY AND CONCLUSIONS

A series of 32 infants and children with congenital syphilis and 4 children with early acquired syphilis were treated for five days by massive dosage of mapharsen intravenously.

The spirochetosis of congenital syphilis produces widespread changes more resistant to treatment than acquired syphilis.

Pediatric care must be exacting and the patients must demonstrate their ability to take food and main-

The work to date is very encouraging, but further study is necessary before the method should be recommended for general use.

5612 West Madison Street

ABSTRACT OF DISCUSSION

DR SAMUEL J. HOFFMAN, Chicago: I believe you will agree that the problem of treating congenital syphilis is entirely different from that of adult syphilis possibly because of the uncertain line of demarcation of stages in the former. In congenital syphilis it frequently takes weeks and months before a definite diagnosis is established. During this period valuable time is lost while the disease progresses. It is my hope that we may learn to diagnose congenital syphilis much earlier than we are doing today. The plan is to study placentas, cords, roentgenograms of the bones and the serologic reaction of mother and infant. A comparison of the titer of mother and infant by the quantitative Kahn method is of much value. If the mother has 60 Kahn units and the infant 300, we feel that this is more than presumptive evidence that the infant has congenital syphilis. A higher titer in the infant is diagnostic and may be demonstrable before x-ray studies or enlargement of

the abdominal viscera occurs, thus making possible early specific treatment

DR I MICHAEL LEVIN, Chicago The method is not one that the general practitioner or pediatrician can advise to his patient at present. Recognition and thanks are due to many agencies of the state and local health departments, as well as the nursing, social service, laboratory and intern personnel of the Cook County Hospital, who made possible this presentation

MENINGOENCEPHALITIS IN MAN CAUSED BY THE VIRUS OF LYMPHO-GRANULOMA VENEREUM

ALBERT B SABIN, MD
AND
CHARLES D ARING, MD
CINCINNATI

Our purpose in this communication is to present data establishing the virus of lymphogranuloma venereum as a cause of severe meningoencephalitis in man. The capacity of the causative agent of venereal lymphogranuloma (lymphogranuloma inguinale, lymphopathia venerea, Nicolas-Favre disease, climatic bubo, fourth venereal disease) to produce meningoencephalitis after intracerebral inoculation in susceptible experimental animals has been known since the virus was first isolated and identified in 1930¹. However, even in experimental animals meningoencephalitis was not known to occur after inoculation of the virus by peripheral routes without simultaneous trauma to the brain. Signs and symptoms suggestive of involvement of the nervous system during the course of lymphogranuloma venereum in man have been recorded by many observers.² Von Haam and D'Aunoy³ isolated from the cerebrospinal fluid of 2 out of 8 patients with lymphogranuloma venereum viruses which produced meningoencephalitis in mice. These viruses were identified as lymphogranuloma venereum only by the fact that suspensions of the affected mouse brains gave positive cutaneous reactions in patients having this disease. However, there was no clinical evidence of meningoencephalitis in these patients, and their cerebrospinal fluids were cytologically and chemically normal.⁴

In the present study the syndrome presented by the patient was predominantly that of meningoencephalitis. Syphilis, tuberculosis and lymphocytic choriomeningitis were at first considered in the differential etiologic diagnosis. Although enlargement of the inguinal lymph

nodes was present, it was of such a character that it was not regarded as suggestive of lymphogranuloma venereum even by dermatologists with experience in this disease. However, the virus of lymphogranuloma venereum, identified by the type of pathogenicity in experimental animals and by cross immunity tests, was isolated on two occasions from the cerebrospinal fluid, from an inguinal lymph node and from seemingly insignificant lesions on the penis.

REPORT OF CASE

HISTORY AND CLINICAL COURSE

J. B., a Negro aged 25, admitted to the Cincinnati General Hospital Jan 14 1942 was acutely ill with a temperature of 105 F and extreme rigidity of the neck. He was confused and irrational. The antecedent history was obtained from an uncle and subsequently from the patient. He was born and lived in Alabama, but in the past four months he had been shuttling back and forth between Alabama and Cincinnati. He had always been in excellent health but thought that he had had gonorrhea at one time, and "years" ago he had been told that he had "bad blood" for which he was given intravenous injections. Early in June 1941 he noticed the development of verrucous lesions around the corona of the penis. Dr Otis F. Gay, health officer of Butler County, Ala., supplied the following record for this period: "This boy was examined by the local physician for the draft board and was found to have some warts on [around?] the glans penis. These warts had the general characteristics of verruca vulgaris and repeated Wassermann tests were negative nor could gonorrhea be detected. At this time there were no open lesions nor regional glandular enlargement. He was admitted to our venereal disease clinic in the hope that a few doses of neosarsphenamine might prove of benefit as is sometimes the case with the common wart. He received approximately twelve injections of 0.6 [Gm] each at weekly intervals without any apparent benefit."

In mid-December some of the warts began to drop off leaving behind tender ulcerated areas and he recalled having had sexual intercourse about December 11 and 25. He was not aware of any inguinal adenopathy. About this time, in the middle of December, a headache and cough developed, both of which persisted until admission to the hospital. At the onset, the headache was mild and generalized, although two days later he was troubled with dizziness and vomiting. Despite the headache, which continued to increase in severity, the dizziness and the vomiting, which recurred every two to three days, he continued to be up and about until Jan 13, 1942. On that day he was too ill to arise in the morning and in the evening in addition to his complaint of very severe headache, periods of irrational behavior and "fever" were observed.

On admission to the hospital January 14 he was acutely ill, irrational, confused and difficult to manage. He presented extreme rigidity of the neck, and attempts at passive flexion of the neck brought forth obvious complaints of pain. The Kernig sign was elicited bilaterally and all the reflexes were hypoaactive. On the penis just proximal to the corona there were a number of raw, shallow, somewhat tender ulcers that bled easily, and one wart. In both inguinal regions there were several enlarged lymph nodes which were not larger than 1.5 cm in diameter, discrete, moderately firm but apparently not tender. The cerebrospinal fluid was cloudy and xanthochromic and contained 4,000 white cells, 25 per cent of which were polymorphonuclear leukocytes, 675 red cells per cubic millimeter and a greatly increased amount of protein. The clinical diagnosis was meningoencephalitis.

He was febrile for about seven days with a pulse rate varying from 85 to 110, the blood pressure was 120 systolic and 70 diastolic. Beginning January 21 his temperature was normal but his neurologic condition remained quite severe. He was somewhat more alert, but the rigidity of the neck and the positive Kernig sign remained. All voluntary movements were tremulous, the tremor being particularly noticeable in the lips, the tongue and all extremities. Periods of confusion were a prominent feature of the disease up until February 3. He talked with illusory people and reached for illusory objects

5. von Haam Emmerich. Personal communication to the authors.

There were prolonged periods of muttering delirium in which he would pick at the covers and roll his head from side to side. He had to be restrained constantly until February 3. During this period he also exhibited mild to moderate left facial weakness, bilateral Hoffmann signs, the Oppenheim sign on the right side and paralytic ileus.

On February 3, three weeks after onset of the acute phase of the disease, he became clear mentally, well oriented and entirely cooperative, but he had no memory of his recent illness. This defect in recent memory, which was also evident from the fact that he could not remember test numbers longer than two to three minutes, persisted until February 20. He was usually drowsy, and the neurologic signs previously noted remained, although less severe. By March 5 he had improved sufficiently to be allowed to sit up. When he attempted to sit still and erect there was an involuntary rotary movement of the head and coarse tremor of the hands was observed in the performance of the finger to nose test. On March 11 he

panying table. The fluid was opalescent and somewhat xanthochromic. At the first examination 25 per cent of the 4,000 white cells were polymorphonuclear leukocytes, but these gradually decreased until none were present after February 18. The bulk of the white cells were lymphocytes, although early in the disease, before the diagnosis was known it was noted that an appreciable number of large mononuclear cells were present and that examination of a hanging drop with the oil immersion lens revealed 'colonies' of dancing particles in the cytoplasm of these mononuclear cells. The possibility that these were cells containing colonies of "elementary bodies" of the virus of lymphogranuloma venereum must therefore be considered and it may be worth while looking for such cells in future cases. The virus was isolated from the specimen of cerebrospinal fluid in which these cells were seen. The number of erythrocytes varied from none to a maximum of 800 per cubic millimeter between January 14 and March 16 and none thereafter. It is noteworthy that the sugar was low

Summary of Data on a Patient with Lymphogranuloma Venereum Meningoencephalitis *

Date 1942	Day of Acute Illness	Temperature	Nervous System Signs	Cerebrospinal Fluid				Isolation of Lymphogranuloma Venereum Virus	Complement Fixation (L.V.) Titer (Serum)	Frei Test

J. B., a Negro aged 25, had had headache, cough and malaise since about Dec. 15, 1941; the onset of fever and acute nervous signs appeared on Jan. 13, 1942.

was allowed to be up and about. Two weeks later, March 25, he complained that his legs were not so strong as they had been before his illness, and slight head and intention tremors were still present. Because of the persistence of these neurologic signs as well as of the definitely abnormal character of the cerebrospinal fluid, indicative of a persisting chronic inflammatory process, sulfathiazole by mouth was started on March 26. A considerable drop in the number of cells and in the amount of protein in the cerebrospinal fluid occurred within a week. Two weeks later he was clinically normal and on April 20 he was discharged from the hospital although his cerebrospinal fluid still contained 102 lymphocytes per cubic millimeter and 250 mg of protein per hundred cubic centimeters. On June 11 he returned to the clinic and stated that he was working. Clinically there were no abnormalities but his cerebrospinal fluid still contained 52 lymphocytes per cubic millimeter and 110 mg of protein per hundred cubic centimeters. He failed to return to the clinic subsequently and thus far has not been located.

CLINICAL LABORATORY DATA

Cerebrospinal Fluid—Nineteen lumbar punctures were performed between January 14 and June 11, 1942, and the essential findings on many of these specimens are shown in the accom-

(17 mg and 20 mg per hundred cubic centimeters) on two occasions early in the disease and the chloride content was subnormal for more than two months; the lowest value having been 450 mg of sodium chloride per hundred cubic centimeters. It is also of interest in this connection that the Levinson and tryptophan tests which are supposed to be indicative of tuberculous meningitis, were positive early in the course of the disease. Nine colloidal gold tests from February 5 to June 11 gave typical first zone curves, precipitation being complete in the first 5 to 8 tubes between February 5 and April 9, and the June 11 reaction was still 5555432000. The Wassermann reaction was negative on five occasions. Cultures on ordinary mediums were negative on four occasions.

Blood—On January 14 the hemoglobin was 12.5 Gm, the red cells numbered 4,700,000 and the leukocytes 15,000 with 69 per cent neutrophils. Leukocytosis was maintained at about this level through February 1. Thereafter, the number of leukocytes ranged between 6,800 and 9,700 per cubic millimeter. The blood urea nitrogen was 23 mg per hundred cubic centimeters on January 14 and on February 19 the total nonprotein nitrogen was 28 mg. On February 5 the plasma content of chlorides was 512 mg per hundred cubic centimeters while that of the cerebrospinal fluid obtained simultaneously was 552

mg On February 19 the total serum protein was 7.68 Gm, albumin 4.73 Gm and globulin 2.95 Gm, with an albumin globulin ratio of 1.6. The Kahn test on the blood gave a negative result on January 14 and February 19. The complement fixation test for gonorrhea was negative on February 21, this was done because a urethral smear at this time revealed gram-negative diplococci. A blood culture was negative on January 14.

Urine and Stools—The urine contained small amounts of albumin on January 14 and 21 and February 12 and 15, but was normal on January 31 and February 7 and 10 and subsequently. The stools gave a positive guaiac reaction for blood on January 14 and February 6.

Röntgenograms—Examination of the chest on January 14 revealed increased markings throughout both lung fields, especially toward the bases, it was also noted that a small amount of peribronchial infiltrate may have been present throughout the lower half of the right lung field. A second examination on February 6 revealed no abnormalities.

Cutaneous Tests—The tuberculin test was negative. A number of Frei tests were done in which lygranum as well as human antigens was used, all of which gave negative results with one exception as indicated in the table.

VIRUS STUDIES

Cerebrospinal Fluid—The first specimen of cerebrospinal fluid obtained on January 16, was immediately injected into 12 mice as follows: 0.03 cc intracerebrally, 0.05 cc intranasally under ether anesthesia and 0.5 cc intraperitoneally into each mouse. Cultures of this fluid taken on ordinary bacteriologic mediums were negative. All the mice remained well for seven days but on the eighth day 7 of the 12 mice exhibited distinct nervous signs (hunched, ruffled hair, ataxic tremulous, convulsive). One of the mice died during a convulsion and another was killed for study on the eighth day. A third mouse with persistent nervous manifestations was killed for study on the twelfth day and a fourth mouse died on the nineteenth day during a convulsion which developed when it was held up by the tail and twirled. The other 3 mice of the first group of 7 had recovered by the twenty-first day. The remaining 5 mice of the original group of 12 became ill on the twelfth day but recovered by the fifteenth day.

The mice that died or were killed presented no gross pathologic changes either in the lungs or viscera or in the brain, and cultures of these tissues taken on ordinary bacteriologic mediums were sterile. Histologically there was a well defined mononuclear and polymorphonuclear meningitis affecting the brain and cord and an ependymitis limited to the ventricles. There were also a focal interstitial pneumonitis and multiple foci consisting of collections of mononuclear cells with large vesicular nuclei, and occasional polymorphonuclear leukocytes, occupying the sites of several cords of parenchymal cells were present in the liver.

Successful passage was accomplished by intracerebral inoculation into new mice of brain suspension of the mice that succumbed or were killed on the eighth day. More than twenty serial passages were carried out before the virus was stored in the frozen state. Beginning with the third passage, the incubation period was reduced to two to three days. Although the morbidity rate was high and mice inoculated with the 10^{-6} and 10^{-7} dilutions developed typical nervous signs (confirmed by the presence of the typical histologic changes and by positive passage), the mortality was never more than 20 per cent even among the mice receiving the lightly centrifuged 10 per cent suspension. Beginning with the thirteenth passage 20 per cent and 40 per cent mouse brain suspensions were used without preliminary centrifugation, and this almost regularly resulted in 90 to 100 per cent mortality, usually in two to five days and more rarely as late as fourteen days. Mice that developed nervous signs following intracerebral inoculation and recovered were immune to reinoculation with the heavy suspensions of virus which were almost regularly fatal for the normal animals. Intraperitoneal or intracutaneous injection or nasal instillation under ether anesthesia of 10 per cent virulent mouse brain suspension was without any apparent effect in mice, and none

of them became immune to intracerebral inoculation one month later. One noteworthy exception was a mouse which showed nervous signs sixteen days after nasal instillation of the virus. The lungs were normal, but the brain showed both encephalitozoon and virus lesions, and many groups of encephalitozoa were clearly seen in all the sections. Passage of the brain tissue in mice yielded only the virus, however, and no encephalitozoa were found in the sections. It would appear possible, therefore, that in the presence of an encephalitozoon infection this virus may localize and produce lesions in the brain after nasal instillation and perhaps after inoculation by other peripheral routes.

Intracerebral inoculation of this virus in guinea pigs and rabbits failed to produce any obvious illness, although slight fever was present for one or two days after injection.

Intracutaneous, subcutaneous and intraperitoneal injection of the virus in guinea pigs resulted in the development of large indurated cutaneous lesions with enlargement of the regional lymph nodes. Filtration of a thoroughly centrifuged virulent 1 per cent mouse brain suspension in broth through Berkefeld filters V, N and W and through a Seitz filter (all impervious to *Bacillus prodigiosus*) was unsuccessful, although the centrifuged material was infective in at least a 10^{-4} dilution.

Three additional attempts were made to isolate virus from the cerebrospinal fluid of this patient. Fluids obtained on January 27 and March 16 yielded negative results clinically, histologically and on passage. The fluid obtained on February 17 (five weeks after acute onset) produced clinical signs in 3 of 10 mice after an incubation period of twelve to seventeen days, and the presence of the same virus was confirmed by microscopic examination and by several positive passages.

Lesions on Penis—After the foreskin was pulled back the penis was thoroughly washed with sterile isotonic solution or sodium chloride, and some of the minute shallow ulcers and pseudoherpetic lesions just proximal to the glans were scraped with a sterile scalpel and the scrapings transferred to salt solution. The scraped areas also were washed with salt solution collected with a capillary pipet. Since this material, totaling 5.5 cc, was obviously dilute and not sufficiently bacteria free for intracerebral inoculation in mice it was all injected subcutaneously into the inguinal region of the abdomen of 1 guinea pig. The regional inguinal lymph nodes that were examined daily were first definitely enlarged on the eighth day, and by the tenth day there was an indurated inflamed mass 2.5 cm by 2.5 cm and about 1 cm thick adherent to the muscle and skin. A piece was obtained by biopsy for cultures, microscopic examination and passage. The guinea pig survived and had no fever or any other abnormal manifestation. Smears and cultures revealed no bacteria, and histologically the tissue was characterized by definite proliferation of the periglandular connective tissue and capillary endothelium with only sparse infiltration with mononuclear and polymorphonuclear cells. The enclosed lymph node appeared hyperplastic but there were no purulent areas nor was there even an excess of polymorphonuclear leukocytes. Passage of a 10 per cent centrifuged suspension of this tissue subcutaneously in a guinea pig and intracerebrally in 6 mice was positive. A similar mass with enlargement of the regional inguinal lymph nodes developed in the guinea pig, this mass regressed after two weeks and the guinea pig remained well without fever for two months. All the mice showed nervous signs after an incubation period of seven days, and 3 died with convulsions on the eighth, tenth and sixteenth days respectively. This strain of virus underwent twelve serial intracerebral passages before storage and proved to be more virulent than those isolated from the cerebrospinal fluid. The incubation period was usually two days or less and most mice inoculated with the 10 per cent or 20 per cent suspension died in two to six days. It was infective intracerebrally in a dilution of 10^{-6} but few of the mice receiving the 10^{-7} dilution or less died. It produced necrotic cutaneous lesions on intracutaneous injection in guinea pigs but was not pathogenic on intracerebral inoculation in the rabbit.

Penile Wart—On January 31 a wart about 1 cm in diameter was removed from the penis just proximal to the corona. Histologically it had the characteristics described for venereal warts and eosinophilic cytoplasmic inclusions resembling Guarnieri

bodies were found in the epithelial cells, the latter observation confirming Wilson's report of the presence of cosmophilic, cytoplasmic inclusions in genital warts.⁶ Inoculation of a suspension of the wart intracerebrally and intraperitoneally into mice and intracutaneously and subcutaneously in a guinea pig was negative clinically, histologically and on passage, and the recovered animals were not immune to the strain of virus isolated from the cerebrospinal fluid.

Lymph Nodes—An inguinal lymph node (1.5 cm. by 0.8 cm. by 0.5 cm.) weighing about 2 Gm. was removed on February 10. On section there were multiple milium abscesses containing whitish "pus" which was bacterium free on smear and culture. A lightly centrifuged suspension was inoculated intracerebrally in 10 mice and intracutaneously (0.2 cc.) and subcutaneously (1 cc.) in the groin of a guinea pig. All the mice showed nervous signs between two and six days after inoculation, 1 died with convulsions on the eighth day while the others recovered at the end of a month. The guinea pig showed the same large (4 cm. by 4 cm.) indurated adherent mass in the inguinal region and the same cutaneous lesions as were observed after inoculation with the strains of virus isolated from the cerebrospinal fluid and penile scrapings. Ten serial intracerebral passages in mice were carried out before the strain of virus from the lymph node was stored. This virus behaved in every respect like the other two strains.

Since there was some question as to whether or not lymph nodes other than those in the inguinal region were enlarged or affected by the virus, an epitrochlear node which was just palpable was removed on March 3 for microscopic study and animal inoculation. Histologically the lymph node was essentially normal and no virus was demonstrable by mouse inoculation and passage.

Blood—Citrated blood obtained on January 16 (simultaneously with the first specimen of cerebrospinal fluid) was inoculated intracerebrally and intraperitoneally into 10 mice. A virus was not demonstrable, the microscopic examination and passage on the killed mice being negative and the remaining mice being without immunity for the strain of virus isolated from the cerebrospinal fluid.

Identification of the Viruses Isolated—The viruses isolated from the cerebrospinal fluid, the penile lesion and the inguinal lymph node although varying somewhat in virulence were found to be identical in their host range, pathogenicity, pathologic changes produced in the nervous system of the mouse and in their immunologic properties. Mice recovering from infection following intracerebral inoculation with virus from one source were immune to reinoculation not only with the homologous strain but also with the fatal doses of the viruses isolated from the other sources.

The properties of these viruses correspond most closely with those of the virus of lymphogranuloma venereum. A strain of lymphogranuloma venereum virus supplied by Dr. Geoffrey Rake of the Squibb Institute for Medical Research was given intracerebrally to mice, and a number of animals proved to be immune to this virus were thus obtained. These mice were found to be immune also to regularly fatal doses of the virus isolated from this patient, and mice immune to the latter virus were also solidly immune to the virus of lymphogranuloma venereum. No such cross immunity was demonstrable with the virus of lymphocytic choriomeningitis (W. E. strain) was supplied by Dr. Joseph Sinadell of the Rockefeller Institute.)

The recent demonstration by Rake, Eaton and Shaffer⁷ and by Eaton, Martin and Beck,⁸ that the viruses of lymphogranuloma venereum, psittacosis, meningopneumonitis of Francis and Magill⁹ and pneumonitis of Eaton, Beck and Pearson,¹⁰

although all distinct, are sufficiently related biologically and immunologically to warrant their consideration as a single group requires special caution in the final identification of newly isolated strains with similar or related properties. The viruses isolated from this patient, like that of lymphogranuloma venereum differ from the other members of this group in their lower virulence by the intracerebral route in mice and together with the pneumonitis virus of Eaton and his associates by their lack of pathogenicity by the intraperitoneal route. However, when Eaton's pneumonitis virus is injected intraperitoneally in mice it produces immunity to subsequent intracerebral inoculation,¹⁰ while the viruses isolated from our patient and the lymphogranuloma venereum virus do not. Moreover, Eaton's pneumonitis virus is of greater pathogenicity for guinea pigs by the intracerebral or intraperitoneal routes, and the convalescent serum of such guinea pigs is devoid of complement fixing antibodies for the virus of lymphogranuloma venereum.⁸ On the other hand, serum obtained from guinea pigs one month after subcutaneous and intraperitoneal or subcutaneous inoculation with the strains of virus derived from the cerebrospinal fluid and penile lesions of our patient contained complement fixing antibodies for the virus of lymphogranuloma venereum in a titer of 1:15 (The tests were performed by Drs. Morris Shaffer and Geoffrey Rake on serum specimens supplied by us.) These findings, taken together with the complete cross immunity that was demonstrated, left little doubt that the strains of virus isolated from our patient were identical with the lymphogranuloma venereum member of this group of viruses. Furthermore, Dr. Rake has carried out a number of studies with our strains of virus, and he found among other things that "the agent is susceptible to sulfonamide therapy, which would exclude all known members of this group [lymphogranuloma venereum-psittacosis] except lymphogranuloma venereum and Nigg's mouse pneumonitis. The virus goes by the intracerebral route and not by the intraperitoneal route which would exclude Nigg's virus and leave only lymphogranuloma venereum."

Serologic Tests on Patient's Serum—Complement fixation tests with lymphogranuloma venereum antigen¹¹ performed by Drs. Shaffer and Rake on 3 specimens of the patient's serum were positive in serum dilutions of 1:120, 1:240 and 1:240 on January 16, February 6 and March 20 respectively. It is noteworthy that the complement fixation test for lymphogranuloma venereum gave positive while the Frei test gave negative results. The patient's serum also fixed complement (++++) in a serum dilution of 1:32 with the virus of meningopneumonitis in a test performed by Dr. Monroe D. Eaton of the California State Department of Public Health. This is in agreement with the known relationships among the viruses of this group.⁷ Repeated complement fixation tests with the viruses of lymphocytic choriomeningitis, St. Louis and eastern and western equine encephalitis viruses carried out by Dr. J. Casals of the Rockefeller Institute were negative.

Negative results were obtained in attempts to demonstrate neutralizing antibodies even against minimal amounts of the virus isolated from the cerebrospinal fluid in 2 specimens of the patient's serum and in guinea pig convalescent serum by intracerebral inoculation in mice, despite the fact that the serum-virus mixtures had long in vitro incubation, and the most sensitive index of the infection, namely the weight curve, was utilized.

A more detailed account of the properties of the viruses isolated from the patient and of the immunologic studies carried out with them will be published elsewhere in association with Mr. Isaac Ruchman, who assisted in these studies.

COMMENT

The evidence presented in this communication can leave little doubt that the virus of lymphogranuloma venereum can be the cause of severe meningoencephalitis in man. Clinically this disease may be readily confused at certain stages with tuberculous meningitis or lymphocytic choriomeningitis. The fact that lymph

node involvement may be minimal and that the Frei reaction can be negative, as in the present case, indicates that suspicion of this form of meningoencephalitis should not be limited to patients with other obvious manifestations of lymphogranuloma venereum. The clinical manifestations and course of this type of meningoencephalitis will no doubt be found to vary considerably from those presented by our patient. Two recent reports, viewed in the light of our findings, suggest that meningoencephalitis due to the virus of lymphogranuloma venereum may on occasion run a rapidly fatal course. Rajam¹² recorded an instance of death from meningoencephalitis in a man aged 27 in whom the Frei reaction was strongly positive. This complication occurred during the fourth week of the disease, three days after the incision of a bubo. The cerebral signs were heralded by confusion and repeated convulsions, the first fit was followed immediately by coma in which the patient remained until death seventeen hours after the onset of the cerebral signs. Necropsy was not performed. The cerebrospinal fluid was said to have been clear and "under great pressure." It contained 136 white blood cells per cubic millimeter, 90 of which were polymorphonuclear leukocytes and 46 lymphocytes. There were 95 mg of albumin and 25 mg of globulin per hundred cubic centimeters of the cerebrospinal fluid. The Wassermann reaction was negative on the blood and cerebrospinal fluid. Rajam injected 0.1 cc of this cerebrospinal fluid intracutaneously in 2 patients with lymphogranuloma venereum and obtained a positive reaction in both. Another important case, recorded in a few lines (p. 28) in the recent review by D'Aunoy and von Haam,² who stated that it was observed by Dr. R. Schenken in their laboratory, was described as follows: "A woman 45 years of age who had been suffering for some time with inflammatory stricture of the rectum was admitted to the hospital with symptoms of meningeal irritation. These were ascribed to pellagra, a frequent complication of stricture of the rectum. Autopsy and histologic examination revealed a diffuse meningeal reaction with lymphocyte and plasma cell infiltration and localized areas of superficial necrosis. Intracerebral inoculation of emulsions of this brain into white mice produced the typical picture of venereal lymphogranuloma encephalitis. The recovered virus was transmitted through several generations of white mice. Antigens prepared from these infected mouse brains gave positive cutaneous reactions in patients proved to have the disease." Although the evidence adduced in these 2 cases cannot in itself be regarded as complete proof that the virus of lymphogranuloma venereum, and not some other or related virus, was the cause of the meningoencephalitis and death, that would appear to be the most probable explanation, particularly in view of the data presented in the present communication.

The importance of considering the virus of lymphogranuloma venereum as one of the agents causing meningoencephalitis in man and of arriving at an early diagnosis is emphasized by the fact that among the virus infections of the nervous system it is the only one in which there is reason to expect a therapeutic effect from the administration of the sulfonamides. As was stated before, we would suspect this type of meningoencephalitis not only in persons with obvious manifestations of lymphogranuloma venereum but also, as in the pres-

ent case, when only minimal, noncharacteristic enlargement of the inguinal lymph nodes is associated with the nervous manifestations, as well as in instances in which no other etiologic agents can be implicated. The special steps to be taken in a suspected case should include (1) inoculation of several specimens of the cerebrospinal fluid intracerebrally (0.03 cc) and intraperitoneally (1 cc) into groups of 6 to 10 young mice, (2) a complement fixation test on the patient's serum with lymphogranuloma venereum antigen,¹³ (3) the Frei test, (4) a biopsy of suspected lymph node for microscopic examination and animal inoculation. In addition to inoculating mice and guinea pigs, one may also inject bacteria free material into the yolk sac of developing 5 to 7 day old chick embryos.¹⁴ It would be inadvisable, however, to limit the inoculations to eggs since, as in the present case, the particular strain of virus may have a low initial virulence for the chick embryo. It is also important to remember that the serums of persons recovered from psittacosis or atypical pneumonia due to Eaton's virus¹⁰ can fix complement with lymphogranuloma venereum antigen and that positive Frei tests have also been obtained in these cases of atypical pneumonia.⁷ The most conclusive evidence, therefore, may be derived chiefly from the pathogenic properties and immunologic identity of a strain of virus that is isolated from the patient. Finally, whenever this type of meningoencephalitis is suspected it would appear advisable to institute sulfonamide therapy as soon as the cerebrospinal fluid and blood (and if possible lymph node) have been obtained for the diagnostic tests and before the results of those tests are known.

SUMMARY

Severe meningoencephalitis associated with slightly enlarged inguinal lymph nodes in a Negro aged 25 was proved to be caused by the virus of lymphogranuloma venereum. This virus was isolated from one of the inguinal lymph nodes, from seemingly insignificant lesions on the penis and on two occasions from the cerebrospinal fluid. The viruses isolated from these three sources were proved to be identical with one another and with the virus of lymphogranuloma venereum in their pathogenic and immunologic properties. No virus was demonstrated in the blood, in an epitrochlear lymph node or in a venereal wart. The patient's serum obtained three days after the onset of acute nervous symptoms had a complement fixation titer of 1:120 with lymphogranuloma venereum antigen and on two subsequent occasions the titer was 1:240. These positive complement fixation tests were obtained at a time when Frei tests gave negative results.

The signs and symptoms remained severe for about a month after the acute onset, and without any special therapy gradual improvement occurred in subsequent weeks. Ten weeks after the acute onset, however, he still had a slight intention tremor and his cerebrospinal fluid still contained 1,200 white cells per cubic millimeter and 1,400 mg of protein per hundred cubic centimeters. Sulfathiazole therapy was then started and two weeks later he was clinically normal and his cerebrospinal fluid contained 198 white cells per cubic millimeter and 315 mg of protein per hundred cubic centimeters. Five months after the acute onset when he was back at work

and essentially normal his cerebrospinal fluid still had 52 white cells per cubic millimeter and 110 mg of protein per hundred cubic centimeters

The importance of recognizing the virus of lymphogranuloma venereum as one of the causes of meningo-encephalitis in man is emphasized by the fact that among the known virus infections of the nervous system it is the only one in which there is reason to expect a therapeutic effect from the administration of the sulfonamides

DIVERTICULA OF THE MALE URETHRA

REPORT OF TWO CASES

HARRY G. MCGAVRAN, M.D. DETROIT

A diverticulum (from the Latin diverticulum meaning to turn aside) is defined in Dorland's Medical Dictionary as a pouch or pocket leading off from a main cavity or tube. From this broad definition there have been many discussions as to whether or not a pouch is a true diverticulum or a pseudo diverticulum, depending on various criteria.

LeCompte and Herschman¹ give an excellent discussion regarding this problem in relation to urethral pouches. It is not my purpose in this paper to enter into this argument but rather to present 2 instances of unusually large pouches in the anterior urethra of the male which may be called diverticula according to the broad definition.

A review of the literature reveals that these are the first 2 cases to occur following transurethral prostatic resection and that therefore they may be added to the ever climbing list of complications of this surgical procedure. The reported cases of urethral diverticula in the male are still small enough in number to place them in the category of being rare.

Watts² in 1906 was the first in the American literature to make a collection of the reported cases adding at this time a case of his own. He found and classified 16 cases as being congenital and 24 as being acquired. Fernovsky³ in 1930 stated that the number of congenital cases in the literature did not exceed 60.

A careful perusal of the modern literature reveals that instances of acquired diverticula are being reported in increasing numbers in about the same ratio as the increase in the number of cases of congenital origin. From 1930 to the present time more than 40 cases of both the congenital and the acquired type have been reported. In this period the etiology, pathology, symptomatology and treatment have been discussed in sufficient detail to negate the necessity of repetition here. However, since Watts's original classification according to etiology, there has been little change. The classification is presented here so as to place properly the 2 cases to be reported.

A Congenital

B Acquired

1 From dilation of the urethra

- (a) Due to stones in the urethra
- (b) Due to stricture of the urethra

2 With perforation of the urethra resulting from

- (a) Injuries to the urethra
- (b) Rupture of abscess into the urethra
- (c) Rupture of cysts into the urethra

Case material made available by Dr. Harry Culver of Chicago and Dr. Fred H. Cole of Detroit.

REPORT OF CASES

The first case is of exceptional interest because the diverticulum developed under continuous observation.

CASE 1—M. M., a man aged 67, a patient at Harper Hospital from Oct. 24, 1939 until the time of writing, both as a hospitalized patient and as a patient seen in the outpatient department when first seen complained of frequency, dysuria and dribbling progressing over a period of four years. The past history and family history were noncontributory. On physical examination the blood pressure was 190 systolic and 84 diastolic and the temperature, pulse and respiratory rate were normal. General examination was negative except for a slightly enlarged heart. The genitalia were normal. Rectal examination revealed a prostate symmetrically enlarged, 3 plus and uniformly indurated 2 plus probably on an infectious basis. Laboratory tests, October 25, showed that the urine was alkaline, with a specific gravity of 1.010. Tests for albumin and sugar were negative. Microscopic examination was negative. A blood count showed hemoglobin 85 per cent, red blood cells 3,490,000 and white blood cells 12,400 with polymorphonuclear leukocytes 71 per cent, lymphocytes 26 per cent, monocytes 2 per cent and eosinophils 1 per cent. Blood chemistry showed nonprotein nitrogen 38.7 mg. per hundred cubic centimeters and sugar

Fig. 1 (case 1)—Anteroposterior view showing normal urethra proximal to the diverticulum.

0.092 per cent. The Kahn reaction was negative. An electrocardiogram revealed coronary sclerosis with mild myocardial damage.

The patient was hospitalized November 1 for study and preparatory for a possible transurethral prostatectomy. Urethral catheter drainage was started. Cystoscopy revealed enlargement of both the median and the lateral lobe of the prostate. There was a typical, coarsely trabeculated bladder. Urethros-copy revealed a normal urethra.

After five days of catheter drainage a transurethral resection was done. Microscopic examination of the tissue revealed benign hyperplasia. In the postoperative course a prevesical abscess developed which had to be drained. There also appeared a periurethral abscess at the penoscrotal junction which ruptured into the urethra spontaneously after the catheter was removed on the ninth day. The urine was badly infected. Because of the rise in temperature a catheter was reinserted on the seventeenth day for five days. The patient was able to void well after the second removal of the catheter, and his only complaint was partial incontinence. The prevesical incision ceased draining, the penoscrotal area remained flat and non-indurated and the patient was discharged on the forty-first hospital day wearing a rubber urinal.

node involvement may be minimal and that the Frei reaction can be negative, as in the present case, indicates that suspicion of this form of meningoencephalitis should not be limited to patients with other obvious manifestations of lymphogranuloma venereum. The clinical manifestations and course of this type of meningoencephalitis will no doubt be found to vary considerably from those presented by our patient. Two recent reports, viewed in the light of our findings, suggest that meningoencephalitis due to the virus of lymphogranuloma venereum may on occasion run a rapidly fatal course. Rajam¹² recorded an instance of death from meningoencephalitis in a man aged 27 in whom the Frei reaction was strongly positive. This complication occurred during the fourth week of the disease, three days after the incision of a bubo. The cerebral signs were heralded by confusion and repeated convulsions, the first fit was followed immediately by coma in which the patient remained until death seventeen hours after the onset of the cerebral signs. Necropsy was not performed. The cerebrospinal fluid was said to have been clear and "under great pressure." It contained 136 white blood cells per cubic millimeter, 90 of which were polymorphonuclear leukocytes and 46 lymphocytes. There were 95 mg of albumin and 25 mg of globulin per hundred cubic centimeters of the cerebrospinal fluid. The Wassermann reaction was negative on the blood and cerebrospinal fluid. Rajam injected 0.1 cc of this cerebrospinal fluid intracutaneously in 2 patients with lymphogranuloma venereum and obtained a positive reaction in both. Another important case, recorded in a few lines (p. 28) in the recent review by D'Aunoy and von Haam,² who stated that it was observed by Dr. R. Schenken in their laboratory, was described as follows: "A woman 45 years of age who had been suffering for some time with inflammatory stricture of the rectum was admitted to the hospital with symptoms of meningeal irritation. These were ascribed to pellagra, a frequent complication of stricture of the rectum. Autopsy and histologic examination revealed a diffuse meningeal reaction with lymphocyte and plasma cell infiltration and localized areas of superficial necrosis. Intracerebral inoculation of emulsions of this brain into white mice produced the typical picture of venereal lymphogranuloma encephalitis. The recovered virus was transmitted through several generations of white mice. Antigens prepared from these infected mouse brains gave positive cutaneous reactions in patients proved to have the disease." Although the evidence adduced in these 2 cases cannot in itself be regarded as complete proof that the virus of lymphogranuloma venereum, and not some other or related virus, was the cause of the meningoencephalitis and death, that would appear to be the most probable explanation, particularly in view of the data presented in the present communication.

The importance of considering the virus of lymphogranuloma venereum as one of the agents causing meningoencephalitis in man and of arriving at an early diagnosis is emphasized by the fact that among the virus infections of the nervous system it is the only one in which there is reason to expect a therapeutic effect from the administration of the sulfonamides. As was stated before, we would suspect this type of meningoencephalitis not only in persons with obvious manifestations of lymphogranuloma venereum but also, as in the pres-

ent case, when only minimal, noncharacteristic enlargement of the inguinal lymph nodes is associated with the nervous manifestations, as well as in instances in which no other etiologic agents can be implicated. The special steps to be taken in a suspected case should include (1) inoculation of several specimens of the cerebrospinal fluid intracerebrally (0.03 cc) and intraperitoneally (1 cc) into groups of 6 to 10 young mice, (2) a complement fixation test on the patient's serum with lymphogranuloma venereum antigen,¹³ (3) the Frei test, (4) a biopsy of suspected lymph node for microscopic examination and animal inoculation. In addition to inoculating mice and guinea pigs, one may also inject bacteria free material into the yolk sac of developing 5 to 7 day old chick embryos.¹⁴ It would be inadvisable, however, to limit the inoculations to eggs since, as in the present case, the particular strain of virus may have a low initial virulence for the chick embryo. It is also important to remember that the serums of persons recovered from psittacosis or atypical pneumonia due to Eaton's virus¹⁰ can fix complement with lymphogranuloma venereum antigen and that positive Frei tests have also been obtained in these cases of atypical pneumonia. The most conclusive evidence, therefore, may be derived chiefly from the pathogenic properties and immunologic identity of a strain of virus that is isolated from the patient. Finally, whenever this type of meningoencephalitis is suspected it would appear advisable to institute sulfonamide therapy as soon as the cerebrospinal fluid and blood (and if possible lymph node) have been obtained for the diagnostic tests and before the results of those tests are known.

SUMMARY

Severe meningoencephalitis associated with slightly enlarged inguinal lymph nodes in a Negro aged 25 was proved to be caused by the virus of lymphogranuloma venereum. This virus was isolated from one of the inguinal lymph nodes, from seemingly insignificant lesions on the penis and on two occasions from the cerebrospinal fluid. The viruses isolated from these three sources were proved to be identical with one another and with the virus of lymphogranuloma venereum in their pathogenic and immunologic properties. No virus was demonstrated in the blood, in an epitrochlear lymph node or in a venereal wart. The patient's serum obtained three days after the onset of acute nervous symptoms had a complement fixation titer of 1:20 with lymphogranuloma venereum antigen and on two subsequent occasions the titer was 1:240. These positive complement fixation tests were obtained at a time when Frei tests gave negative results.

The signs and symptoms remained severe for about a month after the acute onset, and without any special therapy gradual improvement occurred in subsequent weeks. Ten weeks after the acute onset, however, he still had a slight intention tremor and his cerebrospinal fluid still contained 1,200 white cells per cubic millimeter and 1,400 mg of protein per hundred cubic centimeters. Sulfathiazole therapy was then started and two weeks later he was clinically normal and his cerebrospinal fluid contained 198 white cells per cubic millimeter and 315 mg of protein per hundred cubic centimeters. Five months after the acute onset when he was back at work

and essentially normal his cerebrospinal fluid still had 52 white cells per cubic millimeter and 110 mg of protein per hundred cubic centimeters.

The importance of recognizing the virus of lymphogranuloma venereum as one of the causes of meningo-encephalitis in man is emphasized by the fact that among the known virus infections of the nervous system it is the only one in which there is reason to expect a therapeutic effect from the administration of the sulfonamides.

DIVERTICULA OF THE MALE URETHRA

REPORT OF TWO CASES

HARRY C. MCGAVRAN, M.D., DETROIT

A diverticulum (from the Latin *diverticulum* meaning to turn aside) is defined in Dorland's Medical Dictionary as a pouch or pocket leading off from a main cavity or tube. From this broad definition there have been many discussions as to whether or not a pouch is a true diverticulum or a pseudo diverticulum, depending on various criteria.

LeCompte and Herschman¹ give an excellent discussion regarding this problem in relation to urethral pouches. It is not my purpose in this paper to enter into this argument but rather to present 2 instances of unusually large pouches in the anterior urethra of the male which may be called diverticula, according to the broad definition.

A review of the literature reveals that these are the first 2 cases to occur following transurethral prostatic resection and that therefore they may be added to the ever climbing list of complications of this surgical procedure. The reported cases of urethral diverticula in the male are still small enough in number to place them in the category of being rare.

Watts² in 1906 was the first in the American literature to make a collection of the reported cases adding at this time a case of his own. He found and classified 16 cases as being congenital and 24 as being acquired. Lermovsky³ in 1930 stated that the number of congenital cases in the literature did not exceed 60.

A careful perusal of the modern literature reveals that instances of acquired diverticula are being reported in increasing numbers in about the same ratio as the increase in the number of cases of congenital origin. From 1930 to the present time more than 40 cases of both the congenital and the acquired type have been reported. In this period the etiology, pathology, symptomatology and treatment have been discussed in sufficient detail to negate the necessity of repetition here. However, since Watts's original classification according to etiology, there has been little change. The classification is presented here so as to place properly the 2 cases to be reported.

A Congenital

B Acquired

1 From dilation of the urethra

- (a) Due to stones in the urethra
- (b) Due to stricture of the urethra

2 With perforation of the urethra resulting from

- (a) Injuries to the urethra
- (b) Rupture of abscess into the urethra
- (c) Rupture of cysts into the urethra

Case material made available by Dr. Harry Culver of Chicago and Dr. Fred H. Cole of Detroit.

REPORT OF CASES

The first case is of exceptional interest because the diverticulum developed under continuous observation.

CASE 1—M. M., a man aged 67, a patient at Harper Hospital from Oct. 24, 1939 until the time of writing both as a hospitalized patient and as a patient seen in the outpatient department when first seen complained of frequency, dysuria and dribbling progressing over a period of four years. The past history and family history were noncontributory. On physical examination the blood pressure was 190 systolic and 84 diastolic and the temperature, pulse and respiratory rate were normal. General examination was negative except for a slightly enlarged heart. The genitalia were normal. Rectal examination revealed a prostate symmetrically enlarged, 3 plus and uniformly indurated 2 plus probably on an infectious basis. Laboratory tests, October 25, showed that the urine was alkaline with a specific gravity of 1.010. Tests for albumin and sugar were negative. Microscopic examination was negative. A blood count showed hemoglobin 85 per cent, red blood cells 3,490,000 and white blood cells 12,400 with polymorphonuclear leukocytes 71 per cent, lymphocytes 26 per cent, monocytes 2 per cent and eosinophils 1 per cent. Blood chemistry showed nonprotein nitrogen 38.7 mg per hundred cubic centimeters and sugar

FIG. 1 (case 1)—Anteroposterior view showing normal urethra proximal to the diverticulum.

0.092 per cent. The Kahn reaction was negative. An electrocardiogram revealed coronary sclerosis with mild myocardial damage.

The patient was hospitalized November 1 for study and preparatory for a possible transurethral prostatectomy. Urethral catheter drainage was started. Cystoscopy revealed enlargement of both the median and the lateral lobe of the prostate. There was a typical, coarsely trabeculated bladder. Urethros-copy revealed a normal urethra.

After five days of catheter drainage a transurethral resection was done. Microscopic examination of the tissue revealed benign hyperplasia. In the postoperative course a prevesical abscess developed which had to be drained. There also appeared a perirethral abscess at the penoscrotal junction which ruptured into the urethra spontaneously after the catheter was removed on the ninth day. The urine was badly infected. Because of the rise in temperature a catheter was reinserted on the seventeenth day for five days. The patient was able to void well after the second removal of the catheter, and his only complaint was partial incontinence. The prevesical incision ceased draining, the penoscrotal area remained flat and non-indurated and the patient was discharged on the forty-first hospital day wearing a rubber urinal.

The patient was seen in the outpatient department four and six weeks after discharge from the hospital. He was still wearing the rubber urinal despite the fact that he was able to hold his urine well when the bladder was artificially distended. He was advised at this time against wearing the rubber urinal because it did not fit him, causing pressure on the ventral side of the penis.

Bougies (No 18 French) were passed with ease on these two visits. There was no evidence of periurethral swelling. The patient did not return to the outpatient department for eight weeks. He then returned complaining of an increased incontinence and swelling along the penis. He was still wearing the rubber urinal. Examination revealed a swelling at the penoscrotal junction the size of a lemon. A catheter passed back 3 inches into the urethra drained off 1½ ounces (45 cc) of infected urine with concomitant disappearance of the swelling. The catheter was then passed into the bladder with ease and no residual urine was found. A No 24 French sound was also passed into the bladder with ease.

On March 29, 1940, the patient was again admitted to the hospital for study. Urethrograms (figs 1 and 2) were made and a cystourethroscopic examination was done. The latter revealed an os elongated to 2.5 cm, situated just anterior to the external sphincter and opening into a large diverticulum the size of a lemon. The vesical neck appeared adequate for good urinary passage, and the sphincter reacted normally.

The diagnosis was then established that incontinence was due to a urethral diverticulum exclusively. The sac was resected and the urethra closed over a No 20 Foley catheter. Postoperative convalescence was uneventful, the catheter being removed on the fourteenth day. The patient was discharged from the hospital a week later completely continent. He was seen periodically in the outpatient department and large sized sounds were easily passed.

One year later the patient submitted to cystoscopy and all findings were essentially negative. The patient remained completely continent and voided freely.

Fig 2 (case 1)—Lateral view

CASE 2—G D, a man aged 68 admitted to St. Luke's Hospital, Chicago, May 1, 1942, complained of a swelling at the base of the penis of two years' duration. He had not been seen prior to the development of the lesion. Five years previously he had had two transurethral prostatic resections six weeks apart. Since the second operation he had been totally incontinent and constantly employed a clamp on the penis. The follow-up treatment included the passing of 'large' sounds

biweekly. Two years before admission a swelling of the penoscrotal junction developed. He did not recall any mention of abscess but did note that from then on no sound could be passed. The patient observed that the swelling was always larger just prior to his releasing the clamp. He also noted that manual pressure over the mass always deflated it and produced 1 or 2

Fig. 3 (case 2)—Lateral view showing tip of syringe lying in distal end of the anterior portion of the urethra in the lower right corner

ounces (30 or 60 cc) more of clear urine after the bladder was empty. He sought relief of his incontinence and also of the bilateral inguinal ache present when the bladder was full. It was necessary to open the clamp every two hours day and night.

His past history was essentially negative. Physical and laboratory examinations, including the Wassermann test, were negative except that there was mild hypertension (154 systolic and 90 diastolic) and slight secondary anemia. Urinalysis was negative.

Examination of the genitalia revealed a lemon size mass at the penoscrotal junction, pressure of this mass caused deflation and flow of urine from the urethra. Cystourethroscopy revealed a finely trabeculated bladder of normal capacity and low tonicity. There was a well developed urachal pouch. The bladder neck had been adequately resected, but verumontanum was absent. Halfway down the anterior portion of the urethra there was a well defined os of a diverticulum of large capacity. The os was about 1 cm in diameter. A urethrogram was then made (fig 3).

Because of complete incontinence and clearness of the urine surgery of this sac seemed inadvisable and was not attempted.

COMMENT

These 2 cases parallel each other in all but the time element. Both patients had transurethral prostatic resections and some urethral dilations prior to the development of the diverticula and in both the lesion developed in the anterior portion of the urethra at the penoscrotal junction.

The two lesions were about the same size. The men were practically of the same age level and were admitted with the same complaints of swelling at the base of the penis and incontinence. Both cases come under Watts's classification of acquired diverticula.

In the first case it is easy to follow along the development and to hypothesize the cause. That a periurethral abscess ruptured into the urethra is an established fact. What caused this abscess cavity to expand might be explained on the basis that the rubber urinal worn by the patient pressed against the urethra just anterior to the penoscrotal junction. This served

as a mild obstruction, since no actual intonitic obstruction existed. Thus the urine, under pressure, expanded the cavity to its large proportions. This hypothesis is very similar to that expressed by Carlton.⁴ He believed that the diverticulum described in his case had been caused by pressure exerted on the urethra by a large myofascial hernia. Since the diverticulum in case 1 developed in a known abscess cavity, it may definitely be placed in that subheading of Witts' classification.

The cause in case 2 is more obscure. The urethra was exposed to the same trauma and infection that is transurethral reaction with its usual postoperative infection and dilatation as was that in case 1. That the patient had a small abscess in one of the glands of Littre which escaped detection is entirely possible, since he did have to have an indwelling catheter after his two reactions. Also a small tear in the urethra from the rectoscope, or the passing of sounds, with subsequent weak spots is possible. In either event the penis clamp created the mechanical obstruction necessary to expand the weak spot. Exact classification of the cause in this case must remain doubtful.

The length of time required to create a clinically recognizable diverticulum might be explained as follows:

- 1 By individual variations of the strength of the tissues
- 2 By the size of the original defect
- 3 By pressure of the primary stream from above

In the first case, the bladder was of normal tone. It created a stream of good force, exerting a much greater pressure on a known larger defect, hence the rapid development of this diverticulum. In the second case in contrast there was a bladder of very low tone and the pressure exerted was minimal.

Certainly one would imagine that a penis clamp would be more obstructive than the lip of a rubber animal pressing on the urethra but the misfit of the latter contrivance as worn by the first patient was certainly equally obstructive. The patient did not need a rubber animal as was indicated in his case history but insisted on wearing it.

As the literature in general agrees, operative intervention is the only cure. Operation was chosen in the first case because the diverticulum was the only source of incontinence. Surgery promised a cure and this contention was subsequently borne out.

In the second case the bladder and the bladder neck indicated a true incontinence with a possible neurogenic background so it was decided, as stated previously, that the removal of the diverticulum would not be of benefit. Further studies on this patient were not carried out during this hospital stay and the patient has not been seen in consultation since that time.

THE PROMOTION DEPRESSION

NORRIS B. FLANAGAN, M.D., BOSTON

Much interest has recently been centered on the psychologic effects of the war. The stimulus for this interest seems to rise from two sources. (1) the academic—what are the theoretical factors which cause psychologic illness in response to the stresses of war? and (2) the practical—how can psychologic medicine be utilized to increase the total efficiency of our war effort?

Although there has been much talk about anxiety, neuro-circulatory asthenia and so on I have seen no reference to the entity Adolf Meyer termed "the promotion depression." By this term I understand him to mean a depressed state resulting from a sudden and overwhelming increase in responsibility in a situation similar to that usually met when an individual obtains a promotion in his place of employment.

REPORT OF CASES

While it is not my intent at this point to settle or even quibble about the more fundamental etiologic aspects of depressions I would like to call attention to three cases I have recently seen.

CASE 1—V. P., a man aged 65, conscientious, fastidious, was chief paymaster in a ship building company for twenty-five years. In "normal times" it employed from five hundred to one thousand men, during the recent period of expansion the number rose to eight thousand. His working hours and responsibilities increased, but his staff of assistants increased proportionately. There had been no complaint from his superiors about his work. He, however, became depressed and expressed the idea that the added responsibility caused his depression. His mental content centered about ideas of being inadequate in his work. His physical symptoms were anorexia, insomnia and moderate loss of weight. His past history is relevant in that he had had a similar depression in 1931, when finally, after many years he had been promoted to chief paymaster.

CASE 2—M. O., a man aged 45, a conscientious, careful worker was chief maintenance man in charge of carpenters in a coastwise steamship company for twenty-two years. The company had recently been dissolved, but he was immediately reemployed as a foreman in charge of the construction of a tanker. After three days on the new job he became depressed. He considered himself inadequate and thought he would never be able to work again. His physical symptoms consisted in early morning waking (3 or 4 o'clock), anorexia, impotence and the loss of 12 pounds (5.4 Kg). There had been no previous history of depression.

CASE 3—L. D., a man aged 55, a very particular and reliable employee had taught bookkeeping and accounting in a private business college for eighteen years. Decreased enrolment in the school as the result of Selective Service required that he take on new and unfamiliar courses. While studying to prepare himself for the new work he became depressed. His mental content centered about ideas of being incompetent, inadequate and failing to do his job. There also were suicidal ideas. His physical symptoms included anorexia, insomnia and loss of weight. After a period of hospitalization for six weeks he recovered and was able to adjust to a more routine accounting job.

COMMENT

All three patients show certain common features. The personality of each might be summed up as belonging to the obsessive compulsive type, that is, each was overconscientious, reliable, fastidious in dress and personal habits, and took responsibility seriously. The precipitating situation in each case was a sudden increase in responsibility, in the first 2 cases directly connected with the war effort and in the third indirectly related to it. The reaction, a depressed state, was common to all 3.

It might therefore be concluded that, although it is just to "reward" a faithful and conscientious employee by a "promotion" (or, more accurately a sudden overwhelming increase in responsibility), in certain instances the action may be quite unwise in these urgent times. An employer naturally tends to assign this type of man to the more responsible positions in rapidly expanding factories and shipyards. I should like, however, to hazard the guess that very few of those employers belong to this personality type, more, that they are employers by virtue of the fact that they do not. By definition, a "boss" must be one who can delegate his work and not feel compelled to do it all himself. Since this overconscientious, meticulous type of personality is easily recognized, even by those psychiatrically untrained, this simple psychodynamic observation might be advantageously heeded by company physicians and the lay personnel departments of our industrial plants in the internal organization of their companies and in the placement of employees.

COMPOUND FRACTURES

A REPORT OF TWENTY CASES IN WHICH SULFONAMIDE DRUGS WERE USED
LOCALLY ALMOST IMMEDIATELY AFTER INJURYCHARLES J FRANKEL MD AND ROBERT V FUNSTEN MD
CHARLOTTESVILLE VA

Since the advent of the sulfonamide drugs, infections in compound fractures have sharply decreased. In 1940 we¹ were able to report a large series of cases treated with careful debridement, meticulous cleansing and flushing with isotonic solution of sodium chloride and closure. Our results were seemingly satisfactory. When the local application of sulfanilamide was added to the routine treatment our results were further improved.² Caldwell³ in 1941 called our attention to the all important first moment when he advocated the immediate dusting of the wound with either sulfanilamide or sulfathiazole powder.

During the last twelve months there have been treated at the University of Virginia Hospital 28 compound fractures of long bones, 20 have had adequate follow-up to warrant reporting.

There were 14 fractures of the tibia and fibula, all at the junction of the middle and lower third, 6 fractures of the humerus, 2 of the radius and ulna and 1 of the femur.

One case, a fracture of the humerus, ended fatally six hours after operation. One other humerus was so badly injured as to require amputation, as was 1 tibia. These cases are omitted from the series.

All the patients were seen within the eight hour safe period except the 1 whose femur was fractured, who was brought to the hospital about twenty-four hours after the onset.

Only 2 of the patients were children.

Since all the compound fractures of ward patients are handled by a changing house staff, supervised by a resident, it was found necessary to formulate a compound fracture routine which we insist on being followed minutely.

The most important parts of the routine are as follows: 1 Immediate splinting is done. 2 The wound is sprinkled generously with sulfanilamide or sulfathiazole or a combination of the two. 3 Treatment for shock is instituted. 4 In the operating room a rigid technic of thorough debridement and flushing is followed. Care is taken to discard dirty instruments and drapes before repair is undertaken. 5 Wounds are closed only if they have been seen before or during the eight hour safe period and if no tension is present. 6 Sulfanilamide or sulfathiazole is sprinkled about the wound before closure. 7 After reduction a snug plaster is applied.

Several of the patients lost so much skin that closure was impossible. We have not as yet resorted to immediate skin grafting as advocated abroad. Instead we have followed Trueta's suggestions. When sufficient granulation tissue has formed, we use multiple pinch grafts.

We have been gratified to find that no infection developed in 28 cases. There was no gas or tetanus infection. Nonunion occurred in 1 case. This was a compound comminuted fracture of the humerus in a patient who caught his arm between two freight cars. Much of the bony substance and soft tissues were left at the scene of the accident. Amputation was advised, but the patient refused. Accordingly, he was treated by the Trueta method. At the present time he has a good cosmetic result. With the aid of a brace he can use his arm for minor functions.

All the tibias healed, the period of union varying from sixteen to forty weeks. Despite frequent reports of healing of fractures of the middle third of the tibia in six to eight weeks, we have never been that fortunate. Our closed reductions of simple fractures of the tibia in that area frequently require about sixteen weeks or more.

We do not advocate a general use of closure of compound fracture wounds in war surgery, but we see no reason for adopting any hard and fast method to cover all occasions.

From the Department of Orthopedic Surgery University of Virginia Hospital

¹ Funsten R V and Frankel C J Compound Fractures U S Nav M Bull 38 494 (Oct) 1940

² Frankel C J Compound Fractures Virginia M Monthly 68 483 (Aug) 1941

³ Caldwell G A Orthopedic correspondence with the authors January 1942

There will be many injuries suffered in isolated engagements in which compound fracture wounds can easily be closed. Certainly there is ample evidence from civilian clinics to show that meticulous care, plus chemotherapy locally and orally, can allow one to close most compound fracture wounds with impunity.

SUMMARY

Twenty cases of compound fractures treated by a carefully planned routine, and closure where possible, showed no infection and only 1 nonunion. Eight other cases not reported likewise showed no infection.

The use of sulfanilamide or sulfathiazole sprinkled into the wound at the scene of the accident or on admission to the hospital is a valuable addition to the routine.

THE PREEMINENT IMPORTANCE OF CLINICAL SIGNS IN
THE DIAGNOSIS OF INTESTINAL OBSTRUCTION
IN EARLY INFANCY

HAROLD STADLER MD IOWA CITY

In making a diagnosis of partial intestinal obstruction in infants, radiographic and fluoroscopic barium sulfate studies are helpful. Evidence from such studies is not always conclusive, however. My purpose in this report is to illustrate that the gastrointestinal tract may appear normal by visualization methods even when clinically demonstrable partial obstruction is present. Two cases are cited.

REPORT OF CASES

CASE 1—M K was born on March 12, 1941, her birth weight was 7 $\frac{7}{10}$ pounds (3,490 Gm). She did well for six days and then began to vomit frequently. The stools had changed from the meconium type, and five yellow ones had been passed. The vomiting progressed in severity and persistence, and the vomitus became bile stained. When she was 7 days old one apparently normal bowel movement occurred. Subsequently peristaltic waves were observed to pass from left to right in the gastric area and from right to left just below the umbilicus. The next day no radiologic evidence of obstruction was found when barium sulfate was introduced into the stomach and its course was observed fluoroscopically. However, it was believed that the vomiting together with visible peristalsis constituted probable evidence of obstruction, and so exploratory laparotomy was performed on March 22. The peritoneum was opened under local anesthesia through a right rectus incision. A moderate amount of free peritoneal fluid was present and the stomach was much dilated. An abnormal condition was noted in the duodenal area. The relationship between the structures in the region was unusual, with alteration in the customary course of the duodenum, the exact nature of the abnormality could not be determined without incurring risk of damage to blood vessels. There appeared to be a zone of constriction in the region of the transverse mesocolon. Posterior gastroenterostomy was performed, and the infant's postoperative course was uneventful.

CASE 2—N Z, born Dec 14, 1940, weighed 7 $\frac{1}{2}$ pounds (3,400 Gm) at birth. With difficulty he was fed at the breast for two weeks. Vomiting was frequent and it became progressively more severe. Occasional feedings were retained only to be vomited with subsequent feedings. The vomitus later contained bile and fecal material. On December 23 barium sulfate studies were made, with essentially negative results. The infant's condition became worse from day to day, and the vomiting was unabated. An intestinal pattern became apparent and peristaltic movements were seen. Exploratory laparotomy was performed on December 29. In the region of the transverse colon a portion of the bowel was found to be contracted. The infant's condition was too critical to permit detailed examination, so a double barreled colostomy was done.

COMMENT

A possible explanation for the findings in these 2 cases is that despite the partial obstruction it was possible by means of vigorous peristalsis for the barium sulfate to be pushed beyond the point of stoppage in quantity sufficient to produce what appeared to be a normal status in the radiologic exami-

From the Department of Pediatrics State University of Iowa College of Medicine

ination. The hyperactive peristalsis, visible through the abdominal wall, together with the persistent vomiting, constituted excellent evidence for obstruction. Under such circumstances, one would be forced to accept the clinical evidence as unequivocal, even though the radiologic evidence is lacking.

SUMMARY

The two cases cited relate to infants with partial intestinal obstruction. In 1 patient the site of obstruction was high whereas it was low in the other infant. In both instances the blockage was incomplete, yet the clinical evidence for the diagnosis seemed conclusive. Radiologic studies of the intestine in each instance failed to show any abnormality. Diagnoses were substantiated in each by an exploratory laparotomy. There is a possible explanation for the discrepancy.

THE COCOANUT GROVE DISASTER IN BOSTON

A PRELIMINARY ACCOUNT

N. W. FAXON, MD

AND

E. D. CHURCHILL, MD

Director and Chief, respectively, of the West Surgical Service of the
Massachusetts General Hospital

BOSTON

The Coconut Grove fire started about 10:15 p. m. Saturday, Nov. 28, 1942. The restaurant was crowded with people celebrating the victory of the Holy Cross football team over that of Boston College. Newspaper accounts estimate a crowd of 1,000. On December 6 the official count of the dead reached 498. The dance floor of the main dining room had been cleared for the start of the floor show. Most of the patrons were seated at their tables or crowded in the bar and cocktail lounges.

The first patients arrived at the emergency ward of the Massachusetts General Hospital at 10:30 p. m. Shortly thereafter the hospital was notified of the disaster and asked to be ready to receive a large number of patients. The hospital organization set up under Civilian Defense for the handling of air raid casualties had already been set into operation. The house staff and nurses on duty were called to the emergency ward. The staff teams for burns and resuscitation were summoned. Nurses, social workers and others were notified. By 11:15 approximately the entire organization for the handling of these cases had been assembled. Additional staff and other personnel continued to report up to midnight.

The emergency ward rooms were immediately cleared of all other patients and evacuation of the sixth floor of the George Robert White Building holding 40 beds was begun. Approximately 30 surgical patients, many of them postoperative, were removed in their beds or on foot, if their condition allowed, to other wards.

By 1:30 a. m. 39 casualties had been assembled in beds in the ward. By 1:45 the burns of all patients, as far as shock and asphyxia would permit, had been completely dressed, shock was adequately treated, and asphyxiated patients were receiving oxygen therapy.

RECEPTION

Dead and Living Patients.—Between 10:30 p. m. and 12:45 a. m. 114 casualties were received in the emergency ward, 75 were either dead on arrival or died within five to fifteen minutes after entering the door. It has been impossible to obtain accurate figures

regarding the number that showed some signs of life at entrance as contrasted with those definitely dead. No patient that lived long enough (fifteen minutes at a maximum) to have resuscitation measures applied died during the first twelve hour period.

The Dead.—Seventy-five casualties are classified as dead on arrival. Two members of the house staff examined each body on arrival before death was pronounced. The bodies were then routed directly to an emergency morgue established in a large room known as the Red Brick Corridor. They were placed on the floor and covered with sheets. Some of the dead showed no burns, they had obviously been asphyxiated. Many showed the cherry red color of carbon monoxide poisoning. Others showed burns but death from asphyxia. A few were badly burned, one to such an extent that recognition would have been difficult.

Identification of the dead was started at once and all but two of the men were identified by 5 a. m. Cards, letters and driving licenses made this comparatively easy. One of the unidentified was a waiter who in changing his clothes had left the contents of his pockets in his street suit.

None of the women had anything on their persons which permitted immediate identification. Their outer coats had been deposited in check rooms and they had become separated from their purses and bags. A description of each woman was assembled, detailing clothing, shoes (usually absent), jewelry, height, weight and color of her hair. This proved to be of slight assistance, and identification was made mostly by inspection of the bodies by relatives and friends. This suggests the recommendation of a standard method of identification for women by bracelet, anklet or some similar method.

Identification of all bodies was completed by Thursday, December 3, five days after the disaster.

The Living.—On arrival the 39 living patients showed in addition to their injuries the effects of fright, cold and exposure. Clothing was dripping wet. Rectal temperatures as low as 94° F. were recorded. Exposed surfaces were grimy with smoke and burned surfaces blackened. The majority were quiet and cooperative. Some were stuporous. Others were distinctly manic, requiring three or four attendants to restrain them. In some instances this was due to hysteria, in others to cerebral anoxia. There was little or no evidence of intoxication. The odors of the fire made it impossible to detect alcohol on the breath. Most patients vomited during the first two or three hours. The vomitus was pungent with acid, in some instances smelled of alcohol, and was composed of partially digested food.

IMMEDIATE MANAGEMENT OF PATIENTS

Wet clothing was removed. Burned surfaces (except the face) were covered with sterile towels. Every patient received an immediate subcutaneous injection of morphine sulfate $\frac{1}{4}$ grain (0.016 Gm.). A solution was made by dissolving a large number of $\frac{1}{4}$ grain hypodermic tablets in an equal number of cubic centimeters of sterile water. This was placed in a large syringe and a single needle employed.

Surface Treatment of Burns.—Thirty of the 39 patients had sustained burns of clinical significance, 9 had minimal second degree burns or no surface burns at all. Many of these later showed pulmonary damage.

The burns were treated by a single method. There was no cleansing or debridement. (One patient only

with a second degree burn had superficial cleansing with soap and water to remove carbon from the hands and the face.)

The burned surfaces were covered with fine mesh gauze impregnated with boric ointment. Gauze, sterile mechanics' waste and cotton roller were utilized to form a bulky dressing. This was compressed snugly with elastic bandage to form a pressure dressing. Splints of folded newspaper, as suggested by the Red Cross, were used for the forearms and hands.

The eyes were examined by a resident from the Massachusetts Eye and Ear Infirmary. Seven patients had lesions involving the lower half of the cornea, 5 per cent sulfathiazole ointment was applied and atropine drops were instilled. All eyes were reexamined at 10 a. m. and the corneal lesions evaluated with fluorescein. The sulfathiazole ointment was reapplied.

Plasma—In December 1941, immediately following the attack on Pearl Harbor, the hospital purchased 200 units of Sharp and Dohme dried plasma. This was held in reserve and not used in the present emergency.

April 1, 1942 a blood and plasma bank was organized. On the night of the disaster 391 units (250 cc each) of frozen plasma was on hand and in addition 38 flasks (500 cc) of whole blood. Sixteen units of plasma was started melting. The first plasma was administered at 11 30 p. m. It is estimated that the patients had received 200 to 500 cc of saline solution by that time. Further batches of plasma were prepared as the need was apparent. By 1 a. m. all patients in shock were receiving plasma.

In the first twenty-four hours following the disaster 120 units of frozen plasma was used on 33 patients (an average of 3.6 units per patient). In the first seven days a total of 141 units was administered. In the first seven days sixteen whole blood transfusions were used for patients with reduced oxygen capacity of their blood. Three members of the house staff, two student interns and three nurses staffed the blood bank, three house staff members supervised plasma administration in the ward. Approximately 33 of the 39 patients received plasma in quantities of 1 to 12 units per individual. The largest quantity given to a single patient in the first twenty-four hours was 9 units.

Low blood pressure was the first indication used for plasma administration. As the burns were dressed, surface areas were estimated and used as a further indication. Hematocrit determinations were available at 3 a. m. as an accurate guide to plasma requirement.

In certain instances difficulty was encountered in carrying out the usual intravenous technique. Irrational and maniacal patients dislodged the needle. Transfer from the emergency ward to the sixth floor resulted in displacement of the needle in a few instances. As many as three intravenous sets were required in a few cases to overcome the difficulties presented by small contracted veins. Extensive burns of the extremities limited the sites available for injection.

It is suggested that a wider use of intrasternal infusion might have been advantageous. For patients requiring restraint and during the dressing of extremities, use of the intrasternal route might have proved very helpful.

Laboratory—Hematocrit and serum protein determinations to guide the administration of fluids and plasma were available at 3 a. m. The highest initial hematocrit

reading was 58, the lowest 40. Repeated examinations were recorded at 5 a. m., 10 30 a. m., 4 p. m. and 8 p. m. The highest hematocrit recorded was 65, a woman with extensive surface area burns, still surviving. On Monday four separate determinations were recorded, on Tuesday two, on Wednesday one.

Intake and output have been recorded and all urine specimens preserved for examination.

All temperatures have been rectal.

Other laboratory examinations have been carried out according to the needs of the individual patients. Oxygen and carbon dioxide content of arterial blood, oxygen capacity, nonprotein nitrogen, prothrombin times, blood chloride, phosphorus and sodium and several other determinations have been informative.

Electrocardiograms and vital capacity demonstrations have been done.

Specimens of blister fluid have been aspirated at the time of dressings as well as on entrance. These are being studied chemically and bacteriologically. It is significant that high levels of sulfadiazine are being recorded in this fluid.

Deaths in the Hospital—Seven of the 39 living patients have died. The time of the disaster (10 15 p. m., Nov. 28, 1942) is taken as the base line. The deaths occurred as follows:

From 0 to 12 hours, 0
From 12 to 24 hours, 1
From 24 to 36 hours, 3
From 36 to 48 hours, 1
From 48 to 60 hours, 1
From 60 to 72 hours, 1
Subsequently (1 week), 0

CASE 1—Burns of face, hands, arms, leg. Inhalation of flame and fumes. Profound anoxia. Oxygen therapy from admission. Died at 11 38 a. m., November 29.

CASE 2—Burns of face and hand. Inhalation of flame and fumes. Tracheotomy. Died at 10 16 p. m., November 29.

CASE 3—Burns of face, scalp, hands. Inhalation of flame and fumes. Laryngeal obstruction. Tracheotomy. Died at 1 a. m., November 30.

CASE 4 (wife of patient 1)—Burns of face, hands, chest and back. Inhalation of flame and fumes. Tracheotomy. Died at 1 04 a. m., November 30.

CASE 5—Burns of face and hands. Inhalation of flame and fumes. Died at 4 20 p. m., November 30. Autopsy.

CASE 6—Burns of face, hands, scalp, back. Inhalation of flame and fumes. Tracheotomy. Died at 6 05 a. m., December 1. Autopsy.

CASE 7—Burns of face, hands, arms, back. Carbon monoxide. Inhalation of flame and fumes. Died at 1 48 p. m., December 1. Autopsy.

One week from the disaster 6 patients remain on the danger list. Four of these are seriously ill. One has minimal burns but shows extensive and possibly permanent damage to basal ganglions from carbon monoxide. Of 6 tracheotomy patients, 2 are living.

Chemotherapy—Two Gm of sulfadiazine was given intravenously at 2 a. m. to all patients, including those without surface burns. This was repeated at 10 a. m. Thereafter those able to take the drug by mouth received 1 Gm every six hours. Patients unable to take the drug by mouth received further intravenous medication at 12 noon, at 9 p. m. and every twelve hours thereafter. Blood levels of 5 to 10 mg per hundred cubic centimeters have been established, the average being 7 mg.

All patients were skin tested with globulin tested serum before antitetanic serum was administered. No positive reactions were observed. Three thousand units

of antitetanic serum was given except to Army and Navy personnel who presumably were protected by recent toxoid injections, and 7 patients with serious pulmonary lesions to whom an increment of bronchospasm might have been immediately fatal.

On the evening of the sixth day all patients with a rectal temperature sustained at 101 F or above received 5000 units of penicillin in 5 cc volume administered intramuscularly. This dosage was continued at four hour intervals.

Isptic Technique and Dressings—All personnel in contact with the patients on admission or admitted to the ward have been gowned and masked. Friends and relatives have been limited to one a day for patients on the danger list, and even these were admitted only after the second day. Patients who have become ambulatory and left their bedside to talk with mother or patient have been masked. Priests and clergy, lay visitors, visiting doctors, nurses, housekeeping personnel, all have cooperated in these rigid precautions. No patient has left the floor for X-ray or other examination. Before sweeping, the floor has been moistened.

A solarium has been converted into a dressing room. The floor was scrubbed with strong antiseptic solution, an operating table was installed and the windows were boarded for blackout requirements. Dressings are done with complete aseptic technique. One assistant removes the outer bandages. Others remaining uncontaminated change and reapply the inner dressings. The number of onlookers has been kept at a minimum.

Bacteriology—Bacteriologic studies are available on 30 patients and will be reported later.

It is apparent that the danger of staphylococci contamination both of lungs and of burned surfaces has been widespread. Suppuration to date is minimal. No bacterial pneumonia has occurred. Coagulase positive staphylococci have been recovered from the bronchi of all the patients examined post mortem.

X-Ray Examinations—The incidence of pulmonary complications made it desirable to record progress by frequent radiologic examination of the chest. At 10 30 a m Sunday all patients were examined. Since that time films have been taken twice a day of the patients showing pathologic changes. Films taken on inspiration and expiration have been particularly informative in demonstrating obstructive emphysema.

Pulmonary Complications—A full evaluation of the pulmonary complications must await definitive evidence regarding the nature of the products of combustion that were released by the fire. Whether a preponderance of one specific noxious gas can be established remains to be seen. Both nitrous dioxide and phosgene have been suggested.

AID BY THE SOCIAL SERVICE DEPARTMENT

The superb aid supplied by the Social Service Department represents a chapter in itself. It helped in a variety of ways in the hospital when people were needed who knew the hospital, its personnel and the function of the various departments, who were disciplined by experience in dealing with people emotionally disturbed and in technique of interview and who knew quickly at what point it was necessary to get administrative sanction for action.

Those members of the Ladies' Visiting Committee and War Service who came in to volunteer were valuable because they were people of poise and they knew the hospital. This last is essential for most volunteer service in a disaster. This we have proved.

Two other groups of volunteer service which met these qualifications should also be noted. One, a group of Harvard undergraduates who had been doing volunteer service as orderlies for over six months, some of whom were on service that night and others who came to the hospital on learning of the need. They knew the hospital. The other, a group of Red Cross nurses' aides, most of whom had been trained at the hospital, who came in on Sunday and following days to release nurses from other wards, so that a constant nursing staff of twenty was kept on eight hour duty, or sixty each twenty-four hours in White-6.

As an example of the need for trained social service and volunteer assistance, consider the information desk at the front door. The following problems were of pressing importance: (1) people inquiring about casualties, (2) people offering volunteer service, (3) people asking to be blood donors, (4) calls for listing of casualties from Civilian Defense Headquarters and the Red Cross, (5) calls from telephone operators in other cities and telegrams inquiring about the casualties, (6) doctors and reporters asking to see the injured and inquiring about identification of the dead.

In addition, social service took over the enormous task of interviews with relatives both of the injured and of the dead. It has rendered invaluable assistance in the ward freeing the medical and nursing services for urgent duties with the patients.

GENERAL COMMENTS AND LESSONS LEARNED

1 The value of a well planned and organized telephone service to notify hospital administration, staff, nurses maintenance and department heads was especially emphasized. Ours functioned but can be much improved. Too much thought and planning cannot be given to this service.

2 The necessity of the immediate examination and separation of living and dead at the very entrance of the hospital was realized only after a number of dead had been admitted to the emergency ward. At once two medical house officers were stationed at the emergency ward entrance for this purpose. This is important, and two men should collaborate.

3 The organization and division of staff and nurses into teams for the undressing of patients, the care of clothes and valuables, the administration of morphine, treatment of shock, dressing of burns and wounds, oxygen therapy and surgical procedures such as tracheotomies proved their worth.

4 The importance of concentration of casualties in one group where they can be under concentrated medical treatment and isolation procedures can be set up if needed was clearly demonstrated in this disaster.

A further interesting problem was presented by the abrupt and unexpected confinement in the hospital of 39 seriously injured people of private patient status. Isolation precautions were considered imperative so anxious families and friends had to be reckoned with. Many requests were received for transfer to a private ward, for special nurses and for private surgical and medical care either at the hospital or in other institutions. The policy was immediately announced that visits from family doctors or consultants at the request of patient or family would be welcomed. Wholehearted cooperation by the local medical profession was received. Doctors visited their patients, reassured them and told them under no condition to consider removal. Medical information that might have a bearing on their present condition was gratefully received by the staff.

It was the mature judgment of those responsible that the facilities mobilized for the examination and treatment of the injured were equal to or better than those that could be provided in private care. This overruled all financial considerations and personal wishes of families and friends.

The late (twenty-four hour) appearance of respiratory lesions in the apparently uninjured demonstrated in this disaster the wisdom of hospital treatment for every one until the pattern of the trauma was fully disclosed.

Medical officers from both the Army and the Navy were, of course, desirous of transferring their injured to military hospitals. Full cooperation was attained in doing this only when consistent with the welfare of the patient.

5 One important defect in the casualty organization appeared in an unexpected quarter. It was impossible for those responsible for the care of the survivors to secure adequate information regarding the character of the trauma. The predominant clinical pattern of flesh burns and severe damage to the respiratory tract was apparent by 1 a.m. An inquiry was directed to authorities but no information regarding the disaster could be obtained. The question of poisonous fumes was immediately raised but definitive evidence on this point is still lacking.

Catastrophe organization might well include experts assigned to the scene of disaster to determine the nature of the trauma, the presence of noxious fumes and so on, not solely to fix the responsibility from a legal standpoint but to aid in the treatment of casualties.

Examination of the dead by competent pathologists might well begin immediately and their findings communicated to clinicians.

Autopsies on those dying after clinical appraisal of symptoms are particularly desirable, not only for scientific purposes but to give immediate assistance in the treatment of the living.

6 For the handling of the dead an emergency morgue should be selected in advance, attention being paid to accessibility, windows for ventilation and cooling, and isolation. It should be placed in charge of some responsible person and a police guard obtained as soon as possible. Only persons bearing passes acceptable to the person in charge and to the police should be admitted. The bodies should be arranged in orderly fashion, heads in the same direction and sexes separated, if possible, covered with sheets. Tags numbered consecutively (M G H 1, 2, 3, and so on) bearing the date and the hour of arrival should be attached to the wrist.

The medical examiner or coroner should be consulted as soon as possible and his directions followed. If he so directs, identification of the dead may be carried out. In every instance pocketbooks, letters and the like by which documentary identification is made should be returned to pockets. No jewelry should be removed. If the medical examiner so directs, however, a complete list of all valuables can be made by two persons, one preferably a police officer, the valuables placed in an envelop, signed by the two persons, and placed in a safe.

For corroboration and personal identification, only one group at a time should be admitted. The name, address and relationship of the identifying person should be entered on a numbered tag. No valuables or body should be released without written consent of the medical examiner or the coroner.

An official count and list of the identified dead should be made as quickly as possible and given to police and press.

7 A list of the living, giving name and address, was available by 3 a.m. and given to police and press and was of great value in giving that information to anxious relatives.

8 It is desirable to obtain police assistance speedily to control yard traffic and to guard the hospital corridors and the morgue.

9 The serving of coffee and sandwiches by the dietary department and the Red Cross was valuable in sustaining the energy and morale of workers and comforting waiting relatives and friends.

10 The need for a hospital organization for the handling of emergency disasters and the collection of an ample quantity of emergency supplies is obvious. Thanks to the efforts of the Civilian Defense, we had been made "catastrophe minded." Owing to practice mobilization and widespread information regarding disaster management, every one performed his duties without orders. Although during the first two hours everything seemed to be in confusion because of the numbers of people scurrying about it was obvious to those responsible for organization that every one was acting rapidly, efficiently and intelligently. Furthermore the quantity of supplies on hand proved adequate and no shortage of anything was experienced.

'An emergency anticipated and prepared for ceases to be an emergency.'

HANDBOOK OF NUTRITION XI

THE WATER SOLUBLE VITAMINS

C. A. ELVEHJEM, PH.D.

MADISON, WIS.

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed.

This group of dietary factors is classified as the water soluble vitamins because, like all vitamins, they are required by the body in extremely small amounts and because the individual chemical compounds are soluble in water although the degree of solubility may vary greatly from the sparingly soluble riboflavin to the readily soluble ascorbic acid. These are the only characteristics common to the individual components because their functions in the living cell may differ greatly and their chemical structures may vary from the simple configuration of nicotinic acid to the more complicated molecular structure of thiamine and riboflavin. Based largely on the source material used in early isolation work and the kind of experimental animal employed for the assay, the water soluble vitamins are generally subdivided into the B vitamins and vitamin C, together with related factors.

No attempt will be made to cover in this short summary the vast amount of literature which is accumulating on the water soluble vitamins. A symposium entitled "The Vitamins" published by the American Medical Association in 1939 includes a detailed survey of the facts known at that time. Therefore this chapter will include only a general summary of the more sig-

From the Department of Biochemistry, University of Wisconsin. Dr. Paul L. Favcek helped in the preparation of this manuscript.

nificant facts, and reference will be made to original papers only when they have been published within the past few years. Since this review will stress the nutritional aspects of these vitamins, the description of the chemical aspects of these deficiency diseases will of necessity be limited.

The B complex now is known to consist of at least a dozen separate factors, nine of which can be obtained in crystalline form. Each factor will be discussed separately and in more or less chronological order of its recognition and identification.

THIAMINE

Thiamine hydrochloride is a white crystalline substance readily soluble in water and possessing a nutlike and salty taste and a yeastlike odor. The empirical formula is $C_{12}H_{17}N_4OSCl_2$ and the compound has the following structure:

It is rapidly destroyed in neutral or alkaline solutions because of hydrolytic cleavage into its constituent pyrimidine and thiazole rings, but in acid solutions it can be sterilized for half an hour at 120 C without appreciable loss of activity. In the dry form the vitamin is very stable, and it is not readily destroyed by oxidation. Its activity is rapidly destroyed by sulfite and tract which may explain the loss of thiamine during the sulfuring of fruits.

In foods and in tissues it occurs both in the free form and as thiamine pyrophosphate or coenzyme. In the latter form it functions in the living cell as a coenzyme in carbohydrate metabolism. In a thiamine deficiency the metabolism of carbohydrate is incomplete and pyruvic acid accumulates in the tissues, a condition which is used clinically in determining thiamine insufficiency. Many of the symptoms which have been observed in beriberi may be related to faulty carbohydrate metabolism, although it is still difficult to differentiate an uncomplicated thiamine deficiency from multiple deficiencies. Some of the nerve lesions which have been described in experimental animals suffering from polyneuritis are certainly related to a deficiency of riboflavin, but there is also good evidence that a lack of thiamine may directly cause neuropathologic changes.

The variety of symptoms seen in the human being has been summarized by Spies and Williams¹ and by Jolliffe.² Wilder³ has pointed out that the type of symptoms which develop depends to a considerable extent on the rate at which the deficiency develops, but in all cases the subjects become depressed, irritable, quarrelsome, uncooperative and fearful. An anemia of the hyperchromic type has also been described in a number of thiamine deficient patients.

² Jolliffe Norman. Recent Advances in Clinical Applications of the B Vitamins. J Am Dietet A 17: 5 (Jan) 1941.

³ Wilder R V. Nutritional Problems as Related to National Defense. Am J Digest Dis 8: 243 (July) 1941. Williams R D and Mason H L. Further Observations on Induced Thiamine (Vitamin B₁) Deficiency and Thiamine Requirement of Man. Proc Staff Meet, Mayo Clin 16: 433 (July 9) 1941.

Although the official method for the estimation of thiamine is the rat assay procedure described in the U S P XI, 1939 Supplement, both the thiochrome and yeast fermentation methods are suitable for most foods. The latter methods have the advantage that they can be used for substances of low thiamine content. Only a few foods can be classified as rich sources of thiamine, they include peas, beans, oatmeal, whole wheat, lean pork and peanuts. However, one must not overlook the staple foods such as milk, vegetables and fruits, which may contribute appreciable amounts of thiamine in the diet although the amount per unit of weight is relatively low.

The Food and Nutrition Board of the National Research Council recommends 15 to 23 mg as the daily thiamine allowance for the average adult man. The minimum daily requirement as established by the U S Food and Drug Administration is 1 mg. The requirement is increased in periods of active growth and during pregnancy and lactation. Pathologic conditions such as fevers and hyperthyroidism, in which there is a general increased metabolism, also increase the requirement. The effect of external temperature on the thiamine requirement of young rats has been reported by Mills,⁴ who found the need per unit of

TABLE 1—Vitamin Content of a Few Typical Foods

Food	Milligrams per hundred grams (edible portion)				
	Thiamine	Riboflavin	Nicotinic Acid	Pantothenic Acid	Pyridoxine
Apples	0.025	0.050	0.500	0.050

food to be twice as high at 91 F as at 65 F. Mills⁵ also discusses the relation of these findings to the resistance of persons living in the tropics.

Diets high in fat have a definite sparing action on the requirement of thiamine in both rats and dogs. This is undoubtedly because fat metabolism does not require coenzyme. The human diet may rarely

⁴ Mills C A. Vitamin and Protein Requirements at Different Temperatures. Am J Physiol 133: 390 (June) 1941.

⁵ Mills C A. Environmental Temperatures and Thiamine Requirements. Am J Physiol 133: 525 (July) 1941.

undergo sufficient change in fat content to alter materially the thiamine requirement. Cahill,⁶ studying the urinary excretion of thiamine in human subjects, could find no increase when part of the carbohydrate was replaced by fat.

In table 1 is presented the vitamin content of a few typical foods. It is evident that, aside from pork, oatmeal, whole wheat, enriched bread and peas, at least five to ten servings (100 Gm.) of the individual foods must be consumed daily to meet the minimum daily requirement. Thus it is not a simple task to select a diet containing adequate thiamine without the use of whole grain cereals or enriched flour and bread. It is well known that significant amounts of thiamine may be lost during the preparation of foods because of the fact that the vitamin is readily soluble in water and easily destroyed by moist heat. Under normal conditions there is probably little destruction of thiamine in the digestive tract, although intestinal disturbance may seriously retard the absorption of this vitamin.

Recently a factor destructive of vitamin B₁ has been found in raw fish. Green, Carlson and Evans⁷ observed a type of paralysis in foxes fed diets containing 20 per cent fresh carp and identified the condition as a thiamine avitaminosis analogous to Weinicke's disease. Further studies⁸ on the mechanism of inactivation point to an enzymatic destruction.

RIBOFLAVIN

Riboflavin is a practically odorless, orange-yellow crystalline compound which in water solution shows a characteristic yellow-green fluorescence. The empirical formula is C₁₇H₂₀N₄O₆ with the following structure

This vitamin is rather heat stable, especially in acid mediums, but extremely labile when exposed to light. In nature riboflavin may occur as such, as riboflavin phosphate or as a constituent of specific flavoproteins. These flavoproteins function as important enzymes in tissue respiration. Enzymes known to contain riboflavin include cytochrome reductase, d-amino acid oxidase and xanthine oxidase.⁹ A definite reduction in the tissue concentration of the latter enzymes has been observed in riboflavin deficient animals.¹⁰ Aside from retarded growth in young animals, other symptoms include dermatitis and cataract in rats and characteristic paralysis in chicks. A recent report by Baum,

Michaelis and Brown¹¹ indicates that the incidence of cataract in rats is increased if the diet supplies a small amount (1 to 2 micrograms daily) of riboflavin. Phillips and Engel have shown a specific neuropathologic condition of the main peripheral nerve trunks in chicks on low riboflavin rations. Similar changes were not observed in the rat until the riboflavin deficiency was aggravated by an increased fat content of the diet.¹² Both acute and chronic riboflavin deficiency has been studied in dogs.¹³ On a diet very low in this vitamin a characteristic collapse syndrome and sudden death are observed in six to eight weeks. Prolonged subsistence on a diet low in riboflavin leads to neurologic abnormalities accompanied by myelin degeneration of peripheral nerves and the posterior columns of the spinal cord. Street, Cowgill and Zimmerman¹³ have shown that opacities of the cornea may occur in the dog as well as in the rat.

In man the symptoms include inflammation of the lips, fissures at the corners of the mouth, glossitis, dermatitis and vascularizing keratitis.¹⁴ The ocular symptoms first described by Sydenstricker and his co-workers¹⁴ appear to be very constant and may appear before other symptoms of the deficiency.

The riboflavin content of foods may be determined by measuring the growth response obtained in chicks or rats maintained on basal rations low in the vitamin, but the more rapid microbiologic method of Snell and Strong¹⁵ is now used rather extensively. Chemical methods involving measurement of fluorescence are also being used.¹⁷ Riboflavin is widely distributed in plant and animal materials. Liver, milk and vegetables may be considered the best and most reliable sources in the human dietary. Seeds, which are so important as a source of thiamine, are poor sources of riboflavin.

The Food and Nutrition Board recommends 2.2 to 3.3 mg of riboflavin as the daily allowance for adult males, and the Food and Drug Administration has accepted 2 mg a day as the minimum daily requirement. The limited values in table 1 show that one serving of liver will adequately meet the daily allowance, that 1 quart of milk will supply the minimum requirement, and that one serving of cheese or eggs will supply one fourth of the daily requirement. Sure and Dichek¹⁸ have demonstrated, in the case of rats, that riboflavin has a pronounced beneficial effect on the economy of food utilization for the synthesis of body tissues. In this connection it is interesting to note that Murlin¹⁹ reports the biologic value of proteins in bread is improved in the presence of extra B vitamins.

NICOTINIC ACID

Nicotinic acid occurs as white, needle-like crystals, is nonhygroscopic and stable in air and has the empirical formula $C_6H_5O_2N$. The structural formula of both the acid and the physiologically active amide are shown.

The sensation of flushing and erythema of the skin which is often observed on administration of nicotinic acid is not produced by nicotinic acid amide. Nicotinic acid is a comparatively weak acid, and its alkaline salts in solution show a slightly alkaline reaction. It is stable to autoclaving temperatures when in solution and shows no loss of activity when exposed to dry heat. Owing to numerous objections to the term nicotinic acid, nicotin and niacinamide have been proposed as unobjectionable synonyms for the acid and amide.

In the body nicotinic acid functions as a component of two important coenzymes, coenzyme I or cozymase and coenzyme II which are concerned in both glycolysis and respiration.⁹ The structure of the two coenzymes is very similar, differing only in the number of phosphoric acid units. Coenzyme I is a diphosphopyridine nucleotide, and coenzyme II is a triphosphopyridine nucleotide. In nicotinic acid deficiency it is possible to demonstrate a decreased cozymase content of the liver and muscle tissue. There has been some question about the cozymase content of the blood during deficiency, but all workers²¹ are now agreed that the change if demonstrable is very slight. It is thus impossible to use this method in the diagnosis of nicotinic acid deficiency.

The dog, pig and monkey are the only experimental animals that show typical nicotinic acid deficiency. Blacktongue in the dog was first described by Chittenden and Underhill, and in 1922 Goldberger and his co-workers concluded that blacktongue in dogs was analogous to human pellagra. The early symptoms of pellagra are weakness, lassitude, anorexia and indigestion, followed by sore and ulcerated mouth and diarrhea. The typical dermatitis usually simplifies the diagnosis. A more detailed summary of the symptoms has recently been made by Harris²² and by Youmans.²³ Spies, Walker and Woods²⁴ have shown that infants and children also suffer from nicotinic acid deficiency in areas where pellagra is endemic, although typical lesions are seldom seen in early infancy. Nicotinic acid is now widely used in the treatment of pellagra, but its use is most successful in conjunction with other vitamins and specific natural foods.

The activity of various compounds related in structure to nicotinic acid was investigated by Woolley and his co-workers,²⁵ and it was concluded that only those compounds which may undergo oxidation or hydrolytic conversion to nicotinic acid are active in the dog. Since that time some activity has been observed in human beings with quinolinic acid, pyrazine 2,3 dicarboxylic acid and pyrazine monocarboxylic acid. A recent paper by Dann, Kohn and Handler²⁶ summarizes much of the work on these compounds, and from their results as well as results in this laboratory one may conclude that the activity of these compounds is greatly inferior to that of nicotinic acid.

Since nicotinic acid is not required preformed in the diets of chicks or rats, the dog, originally used by Goldberger and his co-workers for the assay of the antipellagra potency of foods, is the only animal that can be used with any success. Fairly accurate values can be obtained by comparing the growth response obtained by feeding a definite weight of the food with that obtained after giving a standard dose of nicotinic acid. Chemical methods may be used on many foods, and an improved method has recently been described by Dann and Handler.²⁸ A convenient method and one which I have found satisfactory is the microbiologic method of Snell and Wright.²⁹ In general there is good agreement between the results obtained with the three methods except in the case of liver and kidney. The values obtained with the dog assay for these materials are somewhat higher than the values obtained by the chemical or microbiologic methods. The best sources of nicotinic acid include liver, yeast, lean meats and to a lesser extent peanuts, potatoes and vegetables.

It is difficult to establish an exact value for the nicotinic acid requirement of human beings. Balance experiments are complicated by the fact that excess nicotinic acid ingested is excreted not only as nicotinic acid but also as trigonelline and nicotinuric acid.³⁰ The Food and Nutrition Board has suggested 15 to 20 mg as the daily allowance for an adult man, and the minimum requirement has been set at 10 mg a day.

One may readily ascertain from table 1 why pellagra will develop on diets high in cornmeal and patent flour. These materials contain 1 to 1.5 mg per hundred grams, and one would have to consume 1,000 Gm to meet the minimum requirement, which is, of course, impossible. In contrast to corn, wheat contains 5 to 7 mg per hundred grams and would be a reliable source of nicotinic acid if 80 to 90 per cent of the nicotinic acid were not removed during the milling process.³¹ Whole oats is also low in nicotinic acid, but barley is somewhat higher. One serving of liver will supply the daily allowance, and one serving of lean meat will supply about one half of the daily requirement. One hundred Gm of peanuts will supply the requirement. Since

nicotinic acid is a very stable compound there is little destruction during cooking, and the loss is negligible unless the cooking water is discarded

PYRIDOXINE—VITAMIN B₆

The early work on the isolation of vitamin B₆ was described in *The Vitamins* in 1939. Since that time the synthesis of pyridoxine has been described by Harris and Folkers³² and it like thiamine, riboflavin and nicotinic acid, is available in the synthetic form on a commercial basis. Pyridoxine hydrochloride is a white crystalline powder, slightly bitter in taste and odorless, possessing the empirical formula C₈H₁₁O₃NCl. It is separate and distinct from nicotinic acid, although the basic structure in both vitamins is the pyridine ring. The complete structure is

Pyro. • hydrochloride

The mechanism in which vitamin B₆ functions in the living organism is unknown. It, like the previous vitamins discussed, may be related to enzyme systems, but there is no evidence for such a conclusion except the fact that it is rather closely bound to protein. There appears to be a functional relationship between unsaturated fatty acids and the vitamin.³³ McHenry and Gavin³⁴ suggest that pyridoxine brings about synthesis of fat from protein, but the nature of the mechanism is unknown.

Pyridoxine has been shown to be essential in the nutrition of the rat,³⁵ the chick,³⁶ the dog³ and the pig.³⁸ An acrodynia characterized by edema, swelling and denuding of the paws and areas around the mouth and frequent thickening of the ears is associated with pyridoxine deficiency in the rat,³⁹ although it has been demonstrated⁴⁰ that a lack of this vitamin may cause retarded growth without the dermatitis. The microcytic hypochromic anemia in dogs resulting from pyridoxine deficiency reported by Fouts and his co-workers³⁷ has been amply confirmed.⁴¹

No clear cut symptoms resulting from pyridoxine deficiency have been described in man. Spies, Bean and Ashe⁴² have reported an additional improvement

in pellagrins by giving pyridoxine after treatment with nicotinic acid, riboflavin and thiamine. Smith and Martin⁴³ observed a rapid and satisfactory healing of the typical lesions of cheilosis with vitamin B₆ therapy. Although clinical treatment of such conditions as Parkinson's disease, muscular dystrophy and paralysis agitans has been studied, the results are not definite enough to permit postulation of the action of the vitamin or to associate any one of these syndromes with specific lack of pyridoxine in the diet. The human requirement is unknown, but animal experiments indicate that the vitamin B₆ requirement may be about the same as for thiamine, namely, about 2 mg a day.

The most reliable method for determining the pyridoxine content of foods is probably the rat assay method.⁴⁰ Scudi⁴⁴ and Swaminathan⁴⁵ have used chemical methods. Among the best sources are rice bran, liver, yeast cereals, legumes and milk. Whole wheat contains about 0.46 mg per hundred grams, most meats 0.4 to 0.7 mg per hundred grams on the fresh basis,⁴⁶ fresh vegetables about 0.1 mg per hundred grams and milk about 2 mg per quart (liter). Swaminathan⁴⁵ found diets consumed in India to supply 3.5 to 5 mg a day.

PANTOTHENIC ACID

In 1939 the term "filtrate factor" was still used to designate that member of the B complex which prevented dermatitis in chicks. Although the so-called filtrate fractions prepared from liver extract were effective in the prevention of blacktongue in dogs, pellagra in human beings and dermatitis in chicks, it was demonstrated as soon as nicotinic acid was accepted as the antipellagra factor that the activity of these fractions in the prevention of chick dermatitis was not due to the nicotinic acid present but to a separate and distinct vitamin. Shortly thereafter Woolley, Waisman and Elvehjem⁴⁸ and Jukes⁴⁹ independently demonstrated that pantothenic acid which Williams⁵⁰ had shown to be a growth factor for yeast as early as 1933, was similar to the chick antidermatitis factor. The complete synthesis of pantothenic acid was achieved in 1940.⁵¹ The vitamin is now available as the dextro-rotatory calcium salt, which occurs in fine dense white crystals that are odorless and slightly bitter in taste. The empirical formula is (C₁₀H₁₇NO₅)₂Ca. The structural formula for the free acid is

Pantoic acid

Pantothenic acid is fairly stable to moist heat, especially at a neutral pH, but is destroyed by prolonged dry heat. The compound is readily hydrolyzed into the

two component parts in alkaline solution. The compound is widely distributed in nature, but its function in normal metabolism is not known. It does occur in bound form in many tissues, since proteolytic enzymes are needed in order to liberate the compound completely from animal tissues.

Rats placed on diets low in pantothenic acid grow very poorly and develop in a few weeks necrosis of the adrenal cortex, which was first described by Daft and Schrell.⁵² Changes in skin pigmentation (graying) have been observed in many laboratories when black or piebald rats are used. Unna, Richards and Sampson⁵³ have published reproductions of photographs illustrating these fur changes in nutritional achromotrichia. Schaefer, McKibbin and Elvehjem⁵⁴ have produced acute pantothenic acid deficiencies in dogs that are characterized by sudden collapse associated with decreased blood dextrose, increased nonprotein nitrogen and lowered blood chlorides. Severe intussusception in the intestinal tract and fatty livers have also been observed. Phillips and Engel⁵⁵ have reported specific neuropathologic changes of the spinal cord in chicks suffering from pantothenic acid deficiency. Wintrobe⁵⁶ has also found neuropathologic changes in pigs on synthetic diets low in pantothenic acid and other members of the B complex.

In spite of these interesting symptoms in experimental animals little is known about the real significance of pantothenic acid in human nutrition. Spies and his co-workers⁵⁷ conclude from studies based largely on blood pantothenic acid values that pantothenic acid is essential to human nutrition. Krahne and Gordon⁵⁸ have studied the excretion of pantothenic acid in persons on different levels of intake. However, no specific symptoms in man have been correlated with a deficiency of the vitamin. This may be due to the fact that pantothenic acid is widely distributed and that even restricted diets may not be low enough to cause a serious deficiency.

No figures can be given for the daily human requirement. The relatively high amount of pantothenic acid needed to produce good growth in rats on synthetic diets has led to the assumption that the requirement is considerably higher than that of some of the other B vitamins. However, work in this laboratory indicates that the requirement for dogs can be satisfied with 0.10 mg. per hundred grams ration, a level very similar to that of thiamine and riboflavin. According to these results the human requirement may not be far from 5 mg. a day.

The pantothenic acid content of foods may be measured by growth experiments with chicks, but the

microbiologic methods⁵⁹ are now in more general use. Liver is one of the richest natural sources, and if 5 mg. is accepted as the daily requirement 100 Gm. of the fresh liver will meet this requirement. Meats, cereals and milk are all reliable sources. Few studies have been made on the loss of this vitamin during cooking, but the loss may be very similar to that for thiamine, since pantothenic acid is readily soluble in water and not too stable at elevated temperatures. Evidence is available to show that only about one half of the pantothenic acid in whole wheat is lost during the milling process.

CHOLINE

Choline is a colorless viscous fluid, and the more familiar choline chloride is a very hygroscopic white crystalline substance with a salty bitter taste. As expected from its chemical constitution, the compound is not stable to alkali treatment but is stable to acids even at elevated temperatures.

Choline has been recognized for many years as a component part of the phospholipid lecithin, but its functional importance in nutrition was not apparent until Best almost ten years ago demonstrated its role in the prevention of fatty livers in depancreatized dogs.⁶⁰ Choline is now considered an important member of the B complex although Jacobi, Baumann and Meek⁶¹ have demonstrated that synthesis of this substance may occur in the rat.

The function of choline is in some way related to the mobilization of fatty acids in the body, since in its absence liver fat rapidly accumulates. Experiments with the dog and the rat have demonstrated that neutral fat was involved, since fatty livers in rats induced by feeding high cholesterol diets did not respond to choline treatment. The observations of du Vigneaud and his collaborators⁶² that the methyl groups of choline as well as those of methionine and betaine are transferable in the animal organism has led to the postulation that one of the functions of choline is to supply labile methyl groups. McHenry⁶³ states that there is evidence now that choline may function in at least three ways: to stimulate the formation of phospholipids, to make possible the production of acetyl choline or to supply labile methyl groups.

Jukes⁶⁴ has shown that choline is one of the factors required in addition to adequate manganese to prevent slipped tendon in young turkeys. Sure⁶⁵ reports that choline is indispensable for lactation in adult rats and in the prevention of paralysis in suckling rats. Depression of the growth rate when choline is omitted from the diet has been observed in the case of the rat by Richardson, Hogan, Long and Itschner,⁶⁵ in the chick

by Hegsted, Mills, Elvehjem and Hart⁶⁶ and in the dog by Schaefer, McKibbin and Elvehjem⁶⁷

The high requirement of the young rat for choline has been stressed by Griffith,⁶⁸ who previously reported fatty degeneration of the liver, hemorrhagic renal lesions, ocular hemorrhages and regression of the thymus within ten days after the rats had been placed on a choline low but otherwise adequate diet. These results on weanling rats are of special significance in the light of recent findings reported from India⁶⁹ that in 20 to 30 cases prematurely born infants showed definite fatty livers and hemorrhagic kidneys.

Choline forms insoluble compounds with Reinecke's salt, rhodoanic acid and mercury and can be determined chemically by these procedures. Griffith has studied the choline requirement of the weanling rat and finds that under his dietary conditions 4 to 6 mg daily will give protection against fatty livers. By determining the level of test substance necessary to furnish similar protection, a measure of its choline content can be obtained. It is to be remembered that other substances which can furnish labile methyl groups such as betaine and sarcosine can function in a manner similar to choline.

As stated previously, lecithin contains choline, and thus meats, cereals, vegetables and eggs would be considered good sources of choline. Yeast seems to be extremely variable in its content of choline, some yeasts being almost free from the factor and others containing enough to protect against fatty livers when fed at 10 per cent of the ration.

Clinical work on choline is of course very limited, and no conclusions can be made until more extensive studies are carried out. Dr. P. G. Danis reported before the Southern Medical Association at St. Louis in November 1941 that choline was of some value in controlling icterus gravis in infants.

BIOTIN

Although biotin has been recognized as necessary for the growth of micro-organisms for some time, its significance in the nutrition of animals is just in the process of being elucidated. Biotin was first isolated in 1936 by Kogl and Tonnies,⁷⁰ but its complex nature and, more important, its minute concentration in natural products has delayed complete identification of its structure even up to the date of this review. Its empirical formula $C_{10}H_{16}O_3N_2S$ has been found by du Vigneaud⁷¹ to consist of a cyclic derivative of urea which, on oxidation, yields adipic acid.

Both the free biotin and the methyl ester have been prepared and possess crystalline structures. Biotin is a very stable compound, resisting autoclaving with strong mineral acids, and in the form found in natural products is but slowly inactivated with strong alkali. The pure biotin, however, shows appreciable lability to alkali. Both free and bound biotin are inactivated by oxidizing agents.

It has been known for many years that a characteristic syndrome can be produced in rats fed diets containing rather high amounts of raw egg white. Lease, Parsons and Kelly⁷² found that the rabbit and the monkey also exhibited a characteristic dermatitis when fed rations rich in egg whites. As early as 1933 Parsons⁷³ concluded that the injury involved an interrelation between a positive toxicity and a relative absence of a protective factor, and a little later Gyorgy named this factor vitamin H. Birch and Gyorgy⁷⁴ obtained highly potent concentrates of the factor, and in 1940 du Vigneaud, Melville, Gyorgy and Rose⁷⁵ first suggested the identity of biotin and vitamin H.

Gyorgy, Rose, Eakin, Snell and Williams⁷⁶ have now established the presence of "avidin" (an albumin) as the biotin inactivating factor in egg white. Thus it becomes apparent that egg white injury is due to the unavailability of biotin by virtue of being tied up with avidin, in which complex biotin cannot be absorbed from the intestine and is excreted in the feces. Nielsen and Elvehjem, using a more complete ration than had been used in the early work, were able to demonstrate a biotin deficiency in the rat fed 10 per cent levels of egg white. Typical symptoms of "spectacled eye" progressing to general alopecia and, in the later stages, the onset of a spasticity and final death of the animal were recorded. Even the severe symptoms of spasticity were cured when excess biotin (in excess of that which unites with the avidin) was added to the diet. On the synthetic diet without the egg white these workers were unable to demonstrate any signs of biotin deficiency, and it seems probable that under most conditions the rat can synthesize, through the medium of bacteria in the intestine, sufficient biotin for its requirement. Biotin deficiency has been reported in the chick without resorting to egg white diets, which seems to indicate that very limited synthesis of biotin in the intestinal tract must prevail. A typical dermatitis involving the feet was found by Hegsted and his co-workers⁷⁸ to be characteristic of the deficiency in the chick, and Patrick and his co-workers⁷⁹ also have noted similar dermatitis with turkeys on biotin deficient rations.

Biotin can be conveniently determined by use of microbiologic methods of assay in which responses in yeast growth (Snell, Eakin and Williams⁸⁰) or acid production by *Lactobacillus casei* (Shull, Hutchings and Peterson⁸¹) are measured. Biotin is quite ubiquitous in distribution, but liver, kidney, yeast and egg

yolk are the chief sources. It is to be emphasized that in most tissues biotin is present in a "bound" state in which it cannot be extracted by hot water, and autolysis or acid hydrolysis must be employed to realize the true concentration of biotin in these instances. As for the clinical applications of biotin, it is needless to point out the futility of even attempting human experimentation until a great deal more of the fundamental work has been accomplished. As soon as crystalline biotin becomes more generally available, this fundamental work will be forthcoming.

INOSITOL

The position of inositol among the B vitamins is only tentative, but since several workers have obtained responses with this compound, presentation of their work is warranted. Inositol is a crystalline substance with a sweet taste, the formula of which is isomeric with d-glucose. Its structure shows it to be a hexahydroxy cyclohexane.

It is an extremely stable compound resisting strong acid and alkali treatment. It is found in plants, where it occurs as "phytin," a calcium magnesium salt of inositol phosphoric acid. In the body, inositol is found in muscle (accounting for the term "muscle sugar"), brain, blood erythrocytes and eye tissues, but its function is still only a matter of speculation. The relation of inositol to the nutrition of animals was first indicated by the report of Woolley,⁸² who isolated the substance from liver and showed it to be the constituent factor responsible for the cure of mouse alopecia. Later Pavcek and Baum⁸³ were able to demonstrate a growth response and a cure of spectacled eye in rats. The curative action and growth effect of inositol seemed to be related to the amount and type of fat in the diet, since the syndrome was produced on fat free or low butter fat rations and not on those containing 14 per cent Crisco (unpublished data). Sure⁸⁴ has presented data which indicate that inositol may be required by the lactating rat. Martin, Thompson and de Carvajal Ferero⁸⁵ have injected rather low levels (10 mg per kilogram of body weight) of inositol into dogs and found intestinal motility to be greatly increased. A definite growth increment in the chick was obtained on feeding inositol in conjunction with a synthetic ration.⁸⁶ In the rat, inositol was found to have an effect similar to lipocain in preventing the fatty livers produced by the feeding of liver fractions or purified biotin preparations.⁸⁷

Inositol can be determined in tissues and foods by using a microbiologic assay employing a specific strain of yeast as the test organism.⁸⁸ By this method of determination, Williams and his co-workers⁸⁹ have run large numbers of assays on various rat and beef tissues and found spleen, heart, kidney, brain, thyroid and testes to be especially high in inositol. As previously mentioned, inositol in the form of phytin, is present in large amounts distributed throughout the plant kingdom, cereal brans and seeds are exceptionally good sources. No work has been done on the possible significance of inositol in human nutrition.

PARA-AMINOBENZOIC ACID

Another factor which was first recognized through its effect on bacterial growth⁹⁰ and which now shows indication of a vitamin-like action in animals is a rather simple derivative of benzoic acid—para-aminobenzoic acid.

Ausbacher⁹¹ has produced graying of the fur of rats on a synthetic ration which could be cured by the administration of 3 mg of para-aminobenzoic acid daily. It should be mentioned that this achromotrichia was not related to pantothenic acid, since the ration contained an adequate amount of this vitamin. A growth response in chicks maintained on a vitamin K deficient ration was also obtained when 300 micrograms of para-aminobenzoic acid per gram of ration was added. Sure,⁸¹ in experiments involving pregnancy and lactation in rats, has observed definite responses to para-aminobenzoic acid. There is some evidence in clinical experiments that restoration of hair pigment may occur⁹² but more extensive experiments both in animal and in clinical trials are necessary before the vitamin nature of the substance can be clearly established.

OTHER FACTORS OF THE B COMPLEX

Although the nine crystalline factors that have been described include almost all of the B factors required by the rat, the use of the chick as the experimental animal gives evidence for the existence of several additional factors which, because of their water solubility, should be classed under the B vitamins. Schumacher, Heuser and Norris⁹³ have fractionated yeast and obtained two growth factors which could not be replaced in their activity by any of the known B vitamin combinations. The designation of R and S factors was applied to these fractions. The identity of one of these factors with the unknown eluate factor which Stokstad⁹⁴ postulates as being responsible together with pyridoxine for the activity of factor U is quite probable.

Amniocetic acid, arginine and chondroitin were found through the experiments of Almquist⁹⁵ and Heg-

sted⁹⁶ as the factors responsible almost entirely for the growth responses due to cartilage and termed the "cartilage growth factor" by the Wisconsin workers. The amino acid cystine shows indications of stimulating growth when fed to chicks on a synthetic ration, indicating the inadequacy of 18 per cent casein diets in this factor.⁹⁷ The factor required by *Lactobacillus casei* has been shown by Hutchings⁹⁸ to function in the nutrition of the chick, and it is highly probable from the comparison of chemical and other properties that it is identical with the "folic acid" of Williams and his co-workers⁹⁹ and what Stokstad¹⁰⁰ termed a "nucleotide."

The class of water soluble vitamins found in citrus fruits, vegetables and milk include ascorbic acid, vitamin P, the "grass juice factor" and the "milk factor."

ASCORBIC ACID, OR VITAMIN C

Ascorbic acid is a colorless crystalline compound with a mild acidic taste resembling that of citric acid and possesses the empirical formula $C_6H_8O_6$. The structural formula of l-ascorbic acid, the physiologically active isomer, is represented as follows

Ascorbic acid is easily destroyed in vegetables, as illustrated by loss of 50 per cent of the vitamin content of lettuce and spinach when stored at room temperature for several days. Cold storage is an effective means of preserving this factor in vegetables and fruits. Ascorbic acid is very easily oxidized, and its destruction during cooking is probably related to this fact. Neutral or alkaline solutions are more conducive to rapid destruction of ascorbic acid than are acid solutions.

Much evidence for the relation of ascorbic acid to specific enzyme systems is available from *in vitro* experiments, but whether these relationships function in the animal organism is not clear. An important argument against the theory of ascorbic acid functioning as a respiratory catalyst is the failure of deficient tissues to show decreases in respiration.

Deficiencies of ascorbic acid can be demonstrated only in man, the monkey and the guinea pig, the other species possessing the ability of synthesis of the vitamin. In infants, especially those artificially fed, periosteal hemorrhages occurring around the bones of the lower extremities are manifestations of the deficiency, while, in adults, petechial hemorrhages into the skin, bleeding into muscle tissue and bloody diarrhea are not uncommon signs. The relation of ascorbic acid to the restoration of the fertilizing capacity of the bull has been recently reported by Phillips and his co-workers.¹⁰¹ The ascorbic acid content of bull semen gives an index

to the probable potency in breeding, low values or exceptionally high values of ascorbic acid are associated with an unreliable breeding record.

The vitamin can be easily determined by use of the dye 2,6-dichlorophenol indophenol, which is quantitatively reduced by ascorbic acid with the resulting formation of the colorless form of the dye and dehydroascorbic acid. Citrus fruits, spinach, berries, tomatoes and cabbage are excellent natural sources of ascorbic acid.

The recommended daily allowance for an average adult man is 75 mg, while the minimum requirement has been set at 30 mg daily. The high requirement of the infant for this factor is provided for in the high concentration of ascorbic acid found in human milk as compared with cow's milk.

CITRIN (VITAMIN P)

A substance distinct from vitamin C has been reported as existing in paprika and lemon rind by Rusznayak and Szent-Gyorgyi.¹⁰² It has been termed "citron" and found to consist of two flavonone components, hesperidin and demethylated hesperidin, or eriodictin. It has been difficult to demonstrate animal responses to such flavonones, but in several clinical trials definite indications of the functioning of these substances in certain hemorrhagic diseases is available. Szent-Gyorgyi and his co-workers¹⁰³ report improvement of capillary

TABLE 2—Vitamin Content of Commercial Concentrates

resistance and permeability in several cases of vascular purpura. Scarborough,¹⁰⁴ presenting data on 6 patients with generalized vitamin deficiencies, has evidence that intramuscular hemorrhages and gingival bleeding were alleviated by large doses of ascorbic acid, but capillary resistance remained low until vitamin P preparations made from orange juice or orange peel were administered. According to this author there exists a distinction between the spontaneous petechial hemorrhages of vitamin P deficiency and those associated with low intake of ascorbic acid.

Citron, on reduction with magnesium in the presence of concentrated hydrochloric acid, forms a red color. Red is produced also when citron is heated with sodium hydroxide. These reactions have been used by some

workers for the estimation of this substance in fruits and vegetables, but poor agreement in the results points to the nonspecificity of the color tests

GRASS JUICE FACTOR AND MILK FACTOR

On rations permitting good growth in the rat or those adequate for the chick, guinea pigs do not survive, indicating that other unknown factors are still lacking. The factor found in fresh grass which is required by the guinea pig has been called the "grass juice factor" by Kohler, Elvehjem and Hart¹⁰⁵. Evidence for another factor, found in milk, concerned with stomach hemorrhages and ulcers in this animal is suggested by the work of Kohler, Randle, Elvehjem and Hart¹⁰⁶. The usefulness of employing a variety of species of test animals in the elucidation of dietary essentials thus cannot be disputed.

From this short discussion it is obvious that the group of water soluble vitamins includes more than a dozen separate factors, many of which have found an important place in human nutrition. Additional factors have been added to this group within the past two years, and some of these may have an equally important role when they are studied more extensively. I doubt that any one will deny the suggestion that there are several water soluble vitamins left to be identified.

The availability of the several synthetic water soluble vitamins has been of the greatest value in clinical practice, but the common foods still remain the best source of these vitamins in practical nutrition. Aside from the gustatory significance of properly prepared natural foods, the greatest value obtained from their consumption is that they supply the unknown factors along with the known. All the known water soluble vitamins may be obtained from natural foods through proper selection. This selection is not an easy task even with the modern methods of food production and distribution. Some of the modern methods of processing increase rather than decrease the difficulties. Often more emphasis is placed on the mere use of natural foods than on the proper combination of these foods. The few values given in table 1 clearly indicate the fallacy of this emphasis. Different natural foods differ greatly in the amount of any given vitamin which they contain. Thus apples contain 0.02 mg. and pork loin 1.5 mg. of thiamine per hundred grams and both are natural foods. Eggs supply 0.05 mg. and peanuts 13 mg. of nicotinic acid per hundred grams. In addition, any one food may show enormous variations in the amount of the different B vitamins present. Thus oatmeal contains 0.8 mg. of thiamine but only 0.1 mg. of riboflavin per hundred grams, while calf's liver contains 0.4 mg. of thiamine and 3.2 mg. of riboflavin per hundred grams. We still need to use a little ingenuity in compounding a complete diet even from natural foods.

There has been an increasing interest in eliminating the effect of this variation by prescribing vitamin concentrates. In other words, a tablet or a capsule may supply the daily requirement of the vitamins, and any pleasing combination of foods may be consumed for the rest of the day. A survey of the concentrates now on the market shows that this is a dangerous practice and that the composition of the concentrates varies just as much as natural foods. At my request Mrs. Sarah Ellen Wenger has studied the composition of one hundred and nineteen vitamin products manufactured by

thirty-two different companies. The B vitamin content of a few of the products is given in table 2. The thiamine content varies from 0.15 to 50 mg., the riboflavin from 0.005 to 20 mg., the nicotinic acid from 0.005 to 25 mg., and so on. In a single product (No. 37) the thiamine is 18, the riboflavin 0.1, nicotinic acid 100, and vitamin B₆ 0.02 mg. These products may be useful in the treatment of specific deficiencies, but in practical nutrition they give us no greater security than the proper combination of natural foods. Thus we not only need to identify all the essential vitamins but we must give consideration to the distribution of these factors in foods and food preparations as well as the daily human requirements.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER, Secretary

GEM HEARING AID, MODEL V-4, C-186, ACCEPTABLE

Manufacturer: Gem Ear Phone Company, 47 West Thirty-fourth Street, New York

The Gem Hearing Aid consists of a combined microphone and vacuum tube amplifier with crystal receiver, with A and B batteries contained in a paper case.

The microphone and amplifier unit are housed in a molded case measuring 4 by 1 7/8 by 1 inches and weighing 4 3/10 ounces. The battery unit measures 3 3/4 by 3 3/4 by 1 3/8 inches and weighs 10 ounces. The receiver is 3/16 by 1 inch in diameter.

BATTERIES

Voltages and current drains with instrument turned full on are

	Voltage	Current
A battery	1.5 volts	70 milliamperes
B battery	30.0 volts	0.5 to 0.7 milliamperes

ACOUSTICAL GAIN

The instrument has two control knobs at the top of the case marked "Volume" and "Tone". The first is an on and off switch; the second seems to be an auxiliary volume control, since its operation showed no definite effect on the tone quality. The instrument is electrically stable and, with a well fitted earpiece, can be turned to full volume without feedback squeal. Internal noise is fairly low, and the instrument is not unduly sensitive to mechanical shocks.

The following are the orders of magnitude of acoustical gain at full volume shown at different frequencies:

128	256	512	2,048	3,072	4,096
Nil	Nil	15-39	33	33	16 decibels

A hard of hearing subject, with an average hearing loss of 45 decibels over the speech range, reports comfortable loudness for conversational speech at a distance of 5 feet when the "Tone Control" is turned to one half full volume.

ARTICULATION TESTS

The usual word and sentence lists were used with hard of hearing subjects at a distance of 5 feet in a quiet room and showed satisfactory performance.

While substantially made, the instrument is evidently designed for economical construction. It is advertised as being "at a new low in price."

The Council voted to accept the Gem Hearing Aid for inclusion in the list of accepted devices.

BLAST INJURIES

An editorial¹ on the subject of blast injuries, published in the March 14, 1942 issue of *THE JOURNAL*, called attention to Hooker's basic experiments on the physiologic effects of air concussion. Zuckerman concluded from his animal experiments that it is the pressure component of the blast wave which bruises the lungs by a direct impact on the body wall. Surgeon Commander Williams,² in a Hunterian Lecture, discusses some results of research by English naval experimental authorities on the pressure effects produced by gun fire. In these experiments it was found that the maximum blast pressure that can be withstood without loss of efficiency is $2\frac{1}{2}$ pounds per square inch. The physical effect of these pressures has been described by observers as being that of a sudden blow on the chest and abdomen. Williams thinks that the effect of the negative air suction wave cannot be entirely neglected; he refers to Daly's experiments on goats subjected to sudden decrease in air pressure, resulting in lesions of the lungs. According to Williams, the third blast component of mass movement of air or gas is capable of inflicting injury of any degree of severity and is responsible for the shattering effects produced in the immediate vicinity of an explosion. In the water, where mass movement is of a small degree even in close proximity to an explosion, these shattering effects are not seen. The mechanism of blast effects in water is much more simple, as there is only a single wave of pressure to be considered, the reflected wave from the sea bottom being of little importance except in shallow water, where it would practically coincide with the primary wave, assuming that the exposed swimmer is on the surface. The lesions caused in water, therefore, are probably due to a single high pressure wave, and there is no question of a wave descending the trachea or an after-suction wave. Effects on the body of explosions, both in air and in water, are primarily due to the externally applied pressure wave, but in air

both the windage factor and the after-suction waves play their parts.

Internal blast injuries without external marks are rare in Williams's experience, since he has seen only 4 such cases among 1,500 casualties. They had the typical clinical and roentgenologic picture, the predominant symptoms in each case being dyspnea and cough. Symptoms which should lead to suspicion of blast damage to the lungs are hemoptysis, slight or severe, pain in the chest, and a short cough accompanied by dyspnea. A point of great practical importance in the treatment of these cases arises when an anesthetic is required for an associated lesion. Here the choice of anesthesia is limited to local anesthetics or to nitrous oxide-oxygen, possibly preceded by a minimum dose of pentothal sodium or evipal soluble. A spinal anesthetic should never be given when there is any degree of shock and lowered blood pressure. The use of ether or of the barbiturates alone is also barred because of their depressant effects. The clinical manifestations of patients who have suffered from water blast, according to Cameron and his associates,³ vary from slight spinal concussion accompanied by bloody diarrhea to lacerations of the abdominal organs and lungs. The mortality from water blasts is high, and it is quite conceivable that many war casualties are due to this factor alone. These authors point out that in the present war, with its dive bombing and torpedo attacks on ships, often the majority of a ship's crew may find themselves in the water after a ship has sunk. Should a depth charge, mine or torpedo explode in the vicinity there would be grave danger that most of the men would lose their lives. Williams calls attention to the fact that acute abdominal pain and rigidity of the abdominal muscles accompanying blast injury to the abdomen are not indicative of the damage done. There may be gross trauma of the hollow or solid viscera, or the lesions may be so insignificant that a complete recovery may take place in a day or two. It is important to remember that most patients recover without surgical intervention. Authors agree that most blast injuries are multiple. They include concussion of the brain and spinal cord, injury to the lungs or the abdominal contents, rupture of the ear membrane and injury to the eye.

Williams believes that the most important single measure in the treatment of patients with blast injuries of the lungs is the continuous administration of oxygen. For respiratory embarrassment and distressing cough he states that he found heroin $\frac{1}{8}$ gram (0.008 Gm.) most satisfactory, since it does not have the depressant effect of morphine. Administration of sulfanilamide or sulfapyridine in the first twenty-four hours is probably not desirable because of its depressant effect and because these drugs may induce vomiting, which is likely to aggravate the condition. Williams suggests that these

patients with damaged lungs be considered particularly vulnerable to air borne infection. The danger of drop-let infection from nurses and relatives should be minimized by the wearing of masks and by strict attention to nursing hygiene. These patients should not, as far as possible, be placed in a general ward but rather under conditions of isolation.

METABOLISM OF RADIOACTIVE IRON

Reliable quantitative studies of iron metabolism by the use of carmarked radioactive isotopes of natural iron were recently undertaken by Whipple and his co-workers¹ of the University of Rochester. The radio iron used by these investigators was prepared in the University of California by bombardment of ordinary iron atoms (Fe^{56}) with deuterons. The Fe^{59} thus formed decays slowly with the emission of beta rays, the half life of the isotope being forty-seven days, a sufficiently long time for metabolic studies. The amount of the isotope present in a given sample of tissue or body fluid is readily determined by measurement of its radioactivity (Geiger counter).

In their earlier experiments the Rochester physiologists found that in normal dogs the rate of absorption of ingested radioactive iron is practically nil, the iron being given in the form of neutral salts (e.g., ferric ammonium citrate). In a typical experiment 650 mg of radio iron was thus given in eighteen divided doses to a normal dog. Eighty-four hours after the last feeding only 0.24 mg of radio iron was found on complete body analysis, most of this being recovered from the ashed liver. In contrast with this normal non-absorption, relatively large amounts of ingested iron are absorbed from the intestinal contents of anemic dogs. Thus in a dog partially depleted of circulating and fixed tissue iron by repeated bleedings and prolonged maintenance on an iron poor diet, 93 per cent of the ingested iron was demonstrated in the blood stream and ashed viscera five days after the final feeding. Most of the circulating iron was already mobilized in the red blood cells, the liver and the bone marrow being the only fixed tissues containing appreciable amounts.

The rapidity with which ingested radio iron is mobilized in the red blood cells is surprising. Presumably the plasma is the initial site of absorption, from which appreciable amounts of iron are transferred to the red blood cells within a few hours. This is too soon to be accounted for by the formation and release of new erythrocytes.

Physiologists² have long taught that superfluous iron is excreted solely or largely by the colon. This colonic excretion the Rochester experimenters were unable to confirm. Welch and his co-workers³ studied a patient with an ileostomy stoma. They found that feeding large amounts of iron by mouth did not result in demonstrable colonic excretion. Apparently, maintenance of normal iron balance is not a function of the colon but of controlled absorption through the small intestine. Excessive iron is apparently excreted to avoid toxic effects.

Currently reported studies⁴ from the Rochester laboratory are essentially clinical confirmation of results previously obtained on dogs. Thirty-four patients, together with adequate normal controls, were fed radio iron in the form of ferric ammonium citrate. Detailed blood analyses were subsequently made with the Geiger chamber. The patients included 14 pregnant women and a miscellaneous group with anemia and other blood dyscrasias. Among the most significant new observations were those on pregnant women without significant anemia.

These at times showed as much as ten times the normal gastrointestinal absorption of radio iron, i.e., from 16 to 27 per cent of the iron intake. In disease states in which iron stores are known to be abundant, such as pernicious anemia, hemochromatosis, familial icterus and Mediterranean anemia, less radio iron absorption was observed than in normal persons. This occurred in spite of the anemia which accompanied all of these cases except those of hemochromatosis. Also, in spite of the accompanying anemia, chronic infections usually do not show increased utilization of iron.

Whipple and his colleagues conclude that the essential control of iron absorption is determined by the reserve stores of iron in the body rather than by anemia. By some unknown mechanism abundant iron reserves cause

The directing board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians wishes immediately the name of any doctor who is willing to be dislocated for service, either in industry or in overpopulated areas, and who has not been declared essential to his present locality. This is necessary if the medical profession is to be able to meet these needs adequately and promptly. Any physician over the age of 45 who wishes to participate in the war effort in this way should send in his name immediately to the state chairman for the Procurement and Assignment Service in his state.

a gastrointestinal refusal to accept superfluous and potentially toxic iron. Attempts are now being made to determine the physicochemical, hormonal and local cytologic factors determining this exclusion. So far as known, metabolism of earmarked iron is identical with that of natural iron.

Current Comment

MEDALS OF THE ARMY MEDICAL DEPARTMENT

In a monograph recently published by the American Numismatic Society Hume¹ describes a series of twenty-four medals, struck in gold, silver and bronze, that have been awarded in recognition of scientific or academic attainment by members of the United States Army Medical Department. Some of these medals were awarded for work of great importance to our country, they serve also to reflect the quality of the army medical educational system. The Army Medical School, the oldest army service school, possesses the oldest medal in the Army awarded for academic standing. At the time of the war between the states Surg. Gen. William A. Hammond proposed the establishment of such an institution, but it did not then materialize. Surg. Gen. George M. Sternberg, with the support of a later secretary of war, Daniel S. Lamont, established the Army Medical School in 1893. The Army School of Nursing was established in 1918, the Medical Field Service School in 1920, the Army Dental School in 1921 and the Army Veterinary School in 1922. All these schools have medals created as awards for academic attainment. The medals were established by private gift, although accepted by the Army Medical Department and given official recognition. The school of Aviation Medicine also was established in 1922. Hume has reproduced the design of these medals and given brief biographies of some of the recipients. A second group of medals reviewed are those that have been awarded to certain distinguished members of the Army Medical Department. The Gorgas Medal was presented by the American Medical Association at its annual meeting in 1914 to Surg. Gen. William C. Gorgas, "whose genius made possible the construction of the Isthmian Canal." The Congressional Walter Reed Medal honoring the chairman of the army commission whose experiments proved that mosquitoes transmit yellow fever was struck some thirty years after the commission did its work and long after Major Walter Reed had died. Hume reviews again those famous experiments. Another Walter Reed Medal was created by the American Society of Tropical Medicine in 1934 to be awarded to individuals or institutions in recognition of meritorious achievement in tropical medicine. The Bailey K. Ashford Medal was established by Eli Lilly & Co. in 1940 and accepted by the American Society of Tropical Medicine, which was given the right to select the winners. The Wellcome Medal, established by the late Sir Henry Wellcome of London, an American by birth,

has been awarded by the Association of Military Surgeons of the United States annually since 1916 for the best research, discovery, invention, essay or other acts or deeds which the association considers helpful in the attainment of its objects and relating to any phase of medical military affairs and disease control associated with the Army, Navy, Militia and Public Health Service. There have been numerous other awards. The Sedgwick Medal was awarded to Brig. Gen. Frederick F. Russell, who was largely responsible for the introduction and use of typhoid vaccine in the Army. Surgeon General Sternberg was awarded several medals, including one by the American Medical Association, John Shaw Billings, Deputy Surgeon General of the Army and the father of the Army Medical Library, received several awards. This monograph is limited, however, to medals honoring medical officers rather than to medals won by individual medical officers. The award of medals is a time honored method of recognizing merit. Hume's monograph will aid collectors and bring home to many others the scientific accomplishments of United States Army medical officers.

NEW SYNDROME CHARACTERIZED BY GYNECOMASTIA AND ASPERMATOGENESIS

A new syndrome characterized by gynecomastia, aspermatogenesis without atydisia, and increased secretion of follicle stimulating hormone has just been described by Klinefelter and his colleagues.¹ Nine cases are presented. Although these cases are not uncommon, they say, few reports have been found in the literature and no author, they claim, has grouped them as a definite clinical entity. The follicle stimulating hormone excretion in the urine is increased to a degree comparable to that found in castrates. Estrogen excretion was studied in 2 cases and found not to be increased. The 17-ketosteroid excretion level and the development of the accessory sexual organs vary from apparently normal to definitely subnormal. Testicular biopsies were obtained in 7 cases and showed hyalinization of the seminiferous tubules and normal appearing interstitial cells. Breast tissue was examined in 4 cases and showed some ductal hyperplasia with definite proliferation of the periductal connective tissue. Testosterone propionate and progesterone have been tried without success, estradiol dipropionate caused further enlargement of the gynecomastia. Surgical removal of the breast is recommended for cosmetic reasons and if carefully done is satisfactory. From microscopic observations it seems unlikely that anything can be done to correct the aspermatogenesis. For those who suffered from hypogonadism, testosterone therapy is probably indicated. These studies support the view that the testes produce two hormones: (1) androgen from the Leydig cells and (2) X-hormone (inhibin) from the tubules. The gynecomastia is apparently not due to hyperestrogenism or to androgen alone, it may be due to the combination of androgen and lack of inhibin.

THE PEPPER HEARINGS ON
MEDICAL MANPOWER

The Procurement and Assignment Service for Physicians, Dentists and Veterinarians the U S Public Health Service, the Federation of State Medical Boards and the Committee on War Participation of the American Medical Association have all been earnestly concerned with the provision of medical service for the armed forces industry and the civilian population. Plans are well under way to determine actual needs and to meet them. Nevertheless the little committee headed by Senator Pepper continues to hear opinions by various volunteers. Among those who have been heard recently were Dr Gilbert Osincup of Orlando, Fla., president of the Florida Medical Association who apparently did not, however, speak for his society. Dr Kingsley Roberts Dr K C Welden of Wilmington N C, and some representatives of the New York Physicians Forum. It has not seemed worth while to give space in *THE JOURNAL* to verbatim reports of these volunteer testimonies. According to the Washington, D C, *Times-Herald*, Senator Claude Pepper stated that he would put forward a suggestion that uniform laws be enacted to break down the "Chinese wall" preventing exchange of doctors between states. According to the *Times-Herald* he made the statement after his committee conducted a hearing attended by ten persons, including Pepper, Senator Millikin (R) of Colorado, two witnesses two committee clerks and four newspapermen. Apparently Senator Pepper is unfamiliar with the action that has already been taken by the Federation of State Medical Boards urging controlled provisions for temporary licensure during the emergency. Among the extraordinary suggestions that have been made was that of Dr Osincup, who urged that all doctors be taken into the Army given training and then sent back to their home practices until they are needed in the Army.

MORE ABOUT VITAMIN P

Vitamin P is the designation given by Szent-Gyorgyi and his collaborators¹ in 1936 to the substance in lemon peel concerned with the regulation of capillary permeability and fragility. At that time it was suggested that chemically, vitamin P was a mixture of the flavone glycosides hesperidin and eriodictin and called citrin. Since that time data have been accumulated which indicate that crude preparations of citrin do indeed influence the capillary state in both experimental and clinical conditions quite distinct from the action of ascorbic acid. A further important advance in chemical and physiologic knowledge of vitamin P now comes in a preliminary communication² from the University of Southern California School of Medicine. The yellow eriodictin of Szent-Gyorgyi has been demonstrated to be in chemical equilibrium in solution with hesperidin and explains the difficulty encountered by Szent-Gyorgyi and his colleagues in the separation of these substances. That this equilibrium is influenced by the acidity of the solu-

tion was established by transformation of one compound into the other and isolation of each in crystalline form. The eriodictin of Szent-Gyorgyi was established as the chalcone form of hesperidin and this chalcone was demonstrated to be reversibly oxidized and reduced. These properties led to the suggestion that this chalcone might be present in the lemon peel in combination with a protein as part of a tissue enzyme system. It was possible to prove the validity of this suggestion by isolation of the intact protein complex from an aqueous extract of lemon peel. The chalcone-protein complex was found to be easily reduced by sodium thiosulfate and to be reoxidized by oxygen. Moreover, the complex was capable of participating as a hydrogen transporter in the glutamic acid dehydrogenase test system obtained from liver tissue. Since the chalcone is auto-oxidizable it can increase the oxygen consumption of such a respiratory system under aerobic conditions. Preliminary experiments have also indicated that the chalcone exerts a beneficial effect on the state of the capillaries decreasing the fragility and preventing localized hemorrhages. The characterization of the chalcone-protein complex has served to emphasize again the close relationships which may exist between vitamins and certain of the respiratory enzymes. Vitamin P will probably take its place as a component of one of the enzyme systems concerned with hydrogen transport and energy production in plant and perhaps animal tissues.

SODIUM SALTS OF THE SULFONAMIDE
COMPOUNDS

Despite the greater bacteriostatic effect in vitro of sulfadiazine and sulfathiazole and their greater resistance to drug inhibitors when compared with sulfanilamide the latter has been preferred, according to Fox¹ for local use in war wounds compound fractures and the peritoneum. Sulfanilamide has the advantage of relatively high water solubility, which facilitates its ready penetration and spread in the local area and rapid absorption into the circulation. Fox points out, however, that sulfathiazole and sulfadiazine are almost completely ionized in the body fluids whereas sulfanilamide is but slightly ionized. The relative acidity of sulfadiazine suggested that its low water solubility could be increased in a physiologic buffer in which it would exist in large proportions as the extremely soluble ionized sodium salt. The fact that sodium salts of these drugs are only moderately alkaline made feasible their local use. In dogs Fox demonstrated that sodium sulfadiazine in high concentration caused little irritation to the tissues and that, following intramuscular or intraperitoneal implantation, the drug is continuously transferred from the site of implantation to the general circulation over periods of twenty-four to forty-eight hours. Thus the disadvantages in the local use of these more potent bacteriostatic drugs appear to be circumvented by using their more soluble sodium salts. The results of the animal experiments warrant clinical trial of the local application of the sodium salts of sulfathiazole and sulfadiazine.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

THE BUSHNELL GENERAL HOSPITAL

The U S Army General Hospital recently constructed at Brigham City, Utah, has been named in honor of the late George Ensign Bushnell, for many years a distinguished officer of the medical corps, known especially for his clinical and research work on tuberculosis. The Bushnell General Hospital has a capacity at present of nearly 1600 beds, which are not however, limited to the treatment of patients with tuberculosis and most of which as yet have been utilized for general medical and surgical patients. The two story buildings with yellow brick facing are of semipermanent construction. The commanding officer is Col Robert Morris Hardaway, the executive officer Lieut Col V Robert Hirschmann, the registrar Col Paul Quinton Stansell, the director of personnel Major Hans Will Lawrence and the receiving and evacuation officer Major Norman Walter Drey.

The additional professional staff consists of Lieut Col James Shirley Sweeney, chief of the Medical Service, Major Henry George Hollenberg, chief of the Surgical Service, Major Olin Burnham Chamberlain, chief of the Neuropsychiatric Service, Major Francis Patrick Carrigan Jr, chief of the X-Ray Service, and Major Frank B Queen, chief of the Laboratory Service.

Subsection chiefs on medical service are Major Alvin Beckham Mullen, tuberculosis subsection, Major Marsh William Poole, communicable disease subsection, Major Rudolph Alfred Koehler, assistant to chief of medical service, and Capt Jerome S Levy, chief of the gastrointestinal subsection.

Subsection chiefs of the surgical service are Major Max Theodore Schmitker, assistant to the chief of the surgical service, Major John E L Keyes, chief of the eye, ear, nose and throat subsection, Major Ernest Edgar Myers, chief of the orthopedic subsection, Major Leander William Riba, chief of the urology subsection, Major Clyde Strickler Roof, chief of the general surgery subsection, Capt John Merar Walker, chief of the septic surgery subsection, and Capt Ralph Curtis Farrington, chief of the anesthetic and operating subsection.

THE ROCHESTER (N Y) GENERAL HOSPITAL UNIT

The nineteenth U S Army General Hospital Unit, almost all of the medical officers of which were members of the staff of the Rochester General Hospital, has been on duty at Camp Livingston, La. since July 15.

The following medical officers are on duty with the nineteenth general hospital unit:

Col Edward T Wentworth	Capt Conrad E Good
Lieut Col Walter A Tenstermacher	Capt Orrin Greenberg (D D S)
Lieut Col Floyd I Allen	Capt Leonard Horn
Major Robert J Gilbraith (D D S)	Capt Burdette H. Koop (D D S)
Major Fred W Geis	Capt George McLoughlin
Major Jacob D Goldstein	Capt David S Parker Jr
Major Louis A Goldstein	Capt Arthur E. Rappeport
Major Don K. Hutchens	Capt Charles D Reeves
Major John I Kellogg, Jr	Capt Edwin T Tellman
Major George R Levine	Capt Eugene Vernon
Major Ralph Linsman	Capt Frank A Wood
Major William A McElroy	Lieut Beverly W Armstrong
Major Alvah S Miller	Lieut Thomas Boyd Bolitho
Major Christopher Parnall Jr	Lieut David Ennis
Major Libby Pulsifer	Lieut Arthur F Fisher (D D S)
Major Ellis B Solle	Lieut Ernest Foss Jr
Capt Willard J Chapin	Lieut R Grant Howard
Capt Robert L Donald	Lieut Ralph F Jacob
Capt Edward W Douglas	Lieut Jos W McElough (D D S)
Capt Eugene R Dugan	Lieut James B Thompson
Capt Frank S French	Lieut George M Trainor
	Lieut Robert J Willoughby
	Lieut Philip M Winslow

The Rochester General Hospital has also provided medical officers for the Navy, so that at present in all seventy one members of the visiting staff of the Rochester General Hospital have been commissioned in the armed forces.

ROGER BROOKE HOSPITAL

The station hospital at Fort Sam Houston, Texas, has been designated a general hospital and named in honor of the late Brig Gen Roger Brooke of the U S Army Medical Corps.

NAVY

NAVAL HOSPITAL AT PEARL HARBOR CITED FOR SERVICE

Admiral Chester W Nimitz, commander in chief of the Pacific Fleet, awarded a blanket citation of an entire unit, an unusual honor, to the staff of the U S Naval Hospital at Pearl Harbor for its meritorious service on Dec 7, 1941. The citation is as follows:

For meritorious achievement and distinguished service subsequent to the Japanese air attack on the United States Pacific Fleet at Pearl Harbor Territory of Hawaii on December 7 1941. At the time of the attack and afterward this unit displayed conspicuous devotion in the line of duty. Its ability to cope with this disaster was responsible for the successful care of all casualties and the saving of many lives. The professional skill displayed and distinguished service rendered by this Hospital Unit were in keeping with the highest traditions of the naval service.

Capt Reynolds Hayden, M C, U S Navy, now medical officer of the third naval district, was in command of the Naval Hospital at the time of the Japanese attack on Pearl Harbor. Capt J J A McMullin, M C, U S Navy, is the present commander of the Pearl Harbor hospital.

LIEUTENANT KEARNEY AWARDED LETTER OF COMMENDATION

Lieut (j g) Edward A Kearney, M C, U S Navy, of the Bronx, New York, has been awarded a letter of commendation by Secretary of Navy Frank Knox for serving with distinction in the U S S *Porter* during the Battle of the Coral Sea.

The letter of award reads as follows:

The Department has been informed of the distinguished service rendered by you as Junior Medical Officer of the U S S *Yorktown* in action against the enemy in the Coral Sea on May 8 1942. On the explosion of an enemy bomb which hit the ship you went immediately to the scene of the damage. As soon as you were able you entered the compartment which was still blazing and full of smoke and under difficult conditions made immediate examinations to determine which of the men were still alive. You personally directed the rescue of those who showed signs of life and immediately rendered medical attention which undoubtedly resulted in saving the lives of several men who were seriously burned or otherwise seriously wounded. Your conduct throughout was in keeping with the best traditions of the Naval Service. For your courage, skill and perseverance on this occasion you are hereby commended.

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

According to *Das Reich* of September 13 the business done by one large Berlin chemist's shop is described as follows. The shop is closed for the lunch hour, and by the time it reopens at 3 p. m. a queue of about thirty people is waiting. Even when the shop reopens, the queue does not disappear, new people constantly take their place in it, and it remains more or less constant until the shop closes for the night. Only a small proportion of the customers at this chemist's shop bring a medical prescription, most of them want preparations which they expect to get without first calling on a doctor. They ask for anodynes, gripe sugar preparations, milk preparations, tonics, vitamin preparations and many different things which they think will make up for imaginary shortcomings of nutrition or compensate the actual or imaginary consequences of some affliction caused by the present conditions. Many of the preparations asked for are not available. If by some chance some food preparation which is in great demand is available in limited quantities, customers frequently return two or three times to the same chemist's shop in order to hoard it. This particular chemist's shop is visited by three thousand people every day. But only roughly one thousand of them actually buy things, and the other two thousand have to leave the shop without having been able to satisfy their frequently extraordinary demands. It is not astonishing, therefore, that the public gets the impression that there are gaps in the supply of medical preparations for the population. But this is not borne out by the actual facts. In reality the average turnover of chemists' shops has increased from 40,000 to 97,000 reichsmarks.

The truth is that, by often exaggerated methods of publicity, factories and chemists before the war had given rise to a veritable mania for medical preparations. Numerous people got used to certain preparations which they thought made life easier for them but which in reality were not only unnecessary but, if used constantly, even harmful. That applies particularly to the large number of anodynes and sleeping drugs, most of which today require a prescription, and to many other preparations which are habit forming. During the war the production of precisely these preparations has been restricted. The fact that they are no longer obtainable has nothing whatever to do with the supply of really vital medical preparations for serious cases of illness.

In view of the large number of brands of even important medical preparations, obviously it is possible to find at least one parallel preparation for almost every existing preparation which will have identical effects, for all these preparations are as a rule made of the same basic materials. Undoubtedly the pharmaceutical industry is performing a great service by producing so many branded preparations, for the chemist would not today be in a position to make up all prescriptions in his own laboratory simply because he lacks the necessary labor. One thing is certain: for all serious cases of illness the medicine which is needed is available even today in every case. In the chemist's shop which has been quoted as an example the war has made large gaps in the staff. Normally this shop employs six qualified dispensers. Today it is working with only two qualified people. Among the eight thousand two hundred chemist's shops in the reich, of which seven hundred are in Berlin, there are many in which the proprietor has been working on his own. To help him, every dispenser who has passed his state examination has to work for four months in a chemist's shop in which the proprietor is working on his own. A large number of preparations have since the outbreak of war been made subject to purchase permits or prescriptions, and the chemist who sells them without either makes himself punishable. Among these are all fats and oils, including castor oil, soaps, certain foreign drugs, all preparations containing estrogenic substances, sleeping drugs, barbituric acid and its derivatives.

Stefani of October 1 reports that during the last two years the minister of foreign affairs sent to Bulgaria and Rumania Prof. Eugenio Morelli, director of the Forlani Institute, who, on the initiative of Italian cultural institutions, gave lectures on the treatment of pleurisy. The Bulgarian minister of war has adopted Professor Morelli's treatment for military hospitals, a

commission of Bulgarian army doctors remained for some time at the Forlani Institute to learn how to apply this treatment.

According to *Pesti Hirlap* of September 3 the military are taking over the Margaret Island club house of the Magyar Athletic Club for use as an orthopedic hospital for soldiers.

Pesti Hirlap of August 30 reports the handing over of the (Tamas) Eszterhazy chateau at Papa for use as a military hospital.

According to NDZ of October 8, the length of the war is beginning to make itself increasingly felt in the sphere of medical supplies. To allay any unfounded fears, the reich leader of pharmacists, Schmierer, has issued a statement emphasizing that there are no worries of a serious nature concerning the supply of medical preparations, supplies are perfectly secure in the future too, provided people do not make unreasonable demands. There are fixed quotas of medicines for civilian consumption which are being distributed by the local chambers of pharmacists according to careful plans. Not only is distribution of almost all preparations controlled, but the preparations themselves are subject to supervision by the competent reich authorities. Transport difficulties such as occurred last winter may of course interrupt supplies temporarily.

Meanwhile the control of medical supplies has entered the stage of planned production. Further measures of rationing are to be expected, and so are measures to relieve the packing difficulties which have repeatedly hampered supplies in the past. In order to restrict the excessive consumption of medicines, certain kinds will be available only on a doctor's prescription. Moreover the excessive and even harmful consumption of medicines must be reduced by means of publicity. It is absurd to carry through a vitamin campaign in the summer when fruit and vegetables are available. It is always the same articles which are in excessive demand, and often quite unreasonable demands have been created by advertising. But for this there would be more than sufficient quantities for everybody who needs them. Hoarding must be avoided at all costs. For instance, in the case of cod liver oil the quantity is sufficient for all cases of need. There are also sufficient supplies of dressings. All difficulties will be overcome if the public behaves reasonably and if the doctors and the pharmacists cooperate closely.

AMERICAN DOCTORS ON ACTIVE
SERVICE IN NEW ZEALAND

An editorial tribute appears in the October issue of the *New Zealand Medical Journal* acknowledging the presence in New Zealand of American physicians on active service. "Their arrival has strengthened and encouraged us, first, because of all it implies to the welfare of our country, and, second, because of the benefits which collaboration with them will bring to our professional work. It is not too much to venture the statement that New Zealand medicine will experience a lasting benefit from this new influence. One and all we welcome the opportunity of meeting American colleagues, whose medical education and traditions are so similar to our own. It is no small matter that our hospitals have already experienced the stimulus of seeing and sharing in the work of senior members of the staff of American institutions whose names are household words throughout the empire. We recognize in our new found friends men of high purpose and great personal charm, with whom we have much in common."

MEDICAL AND SURGICAL RELIEF
COMMITTEE

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York City, furnished supplies during the last month valued at more than \$5,000 to relief agencies and the armed forces. The shipments included 8 emergency medical field sets, 3 operating sets, 1 transfusion set, 2 cystoscopes, 250,000 sulfanilamide tablets, 225 vials of gas gangrene vaccine, 610 vials of insulin and other supplies. These materials were contributed by various pharmaceutical and surgical manufacturing companies.

ORGANIZATION SECTION

MEDICAL ECONOMIC ABSTRACTS

HEALTH INSURANCE IN CANADA

The discussion of health insurance in Canada has followed much the same line as in the United States. The Canadian Medical Association adopted a series of principles that were considered as expressing the attitude of the medical profession in regard to any plan that might be adopted. The opinion of the membership of the association was sought and upward of three thousand replies were received, of which 90 per cent favored the adoption of the principles 'which, over a period of ten years had been studied and revised by the association and its component parts. At a consultation between the Health Insurance Committee of the Canadian Medical Association and the Advisory Committee on Health Insurance established by the dominion government July 17, 1942 the association committee stated that it had but one desire namely to cooperate with constituted authority in devising plans which would provide the best possible medical service for the people of Canada. The Canadian Medical Association is not sponsoring health insurance or any other "group plan" of practice, but the association believes that it has a duty to perform in offering its best advice to any government (national or provincial) which undertakes to promulgate a health insurance scheme. Moreover, by an overwhelming majority vote the medical profession authorized the association to take such action.

The presentation of these twenty health insurance principles 'is not the formulation of a health insurance act but should be regarded as the framework or the planks around which and out of which an act may be built. As has already been stated, the Canadian Medical Association is not advocating health insurance or proposing any draft legislation." With this understanding the following principles were submitted with an explanation and discussion of the reasons why each was approved.

1 That in the provinces where health insurance is established it be administered under an independent health insurance commission, the majority of whom shall be representatives of organized medicine. There should be close cooperation between this commission and the provincial department of public health with a view to making full use of preventive services.

2 That a central health insurance board and local insurance boards be appointed representative of all interested, to advise the responsible administrative authority.

3 That the professional side of health insurance medical service be the responsibility of the organized medical profession through the appointment of a central medical services committee and local medical services committees to consider and advise on all questions affecting the administration of the medical benefit.

4 That the question of the establishment of local areas for health insurance administration be left to the decision of the individual province.

5 That the whole province be served by adequate departments of public health, organized where possible on the basis of provision of individual health supervision by the general practitioner.

6 That regional medical officers to act as supervisors and referees be appointed, paid and controlled by the commission.

7 That medical care for indigents and transient indigents be provided under the plan, the government to pay the premiums of the indigents who then receive medical care under exactly the same conditions as other insured persons.

8 That the plan be compulsory for persons having an annual income below a level which proves to be insufficient to meet the costs of adequate medical care.

9 That the dependents of insured persons shall be included in the medical benefits.

10 That the only benefit under the plan be the medical benefit.

11 That the medical benefit be organized as follows:

(a) Every qualified licensed medical practitioner to be eligible to practice under the plan.

(b) The insured persons to have freedom of choice of medical practitioner and vice versa.

(c) The medical service to be based on making available to all a general practitioner service for health supervision and treatment of disease.

(d) Additional services to be secured ordinarily through the medical practitioner.

(1) (a) Specialist medical service.

(b) Consultant medical service.

(2) Visiting nurse service (in home).

(3) Hospital care.

(4) Auxiliary services—usually in a hospital.

(5) Pharmaceutical service.

(c) Dental service, arranged direct with dentist or on reference.

12 That the insurance fund should receive contributions from the insured, the employer or the insured and the government.

(a) Payment of the premium of the insured in certain proportions to be determined should be made by the employee, employer and government.

(b) Where an insured person has not an employer or where it is not practical for the government to collect from the employer the government should pay in for that insured person what would be the employer's share as well as its own share of the premium.

(c) Where the insured is 'indigent' or has been out of work long enough to come within the scope of the provisions of the act relating to an insured employee the government should assume payment of the full premium.

13 That the medical practitioners of each province be remunerated according to the method or methods of payment which they select.

14 (a) That the schedule of fees in any health insurance scheme shall be the schedule of fees accepted by the organized profession in the province concerned.

(b) That all schedules of fees be under complete control of the organized medical profession in each province.

15 That the contract-salary service be limited to areas with a population insufficient to maintain a general practitioner in the area without additional support from the insurance fund.

16 That no economic barrier be imposed between doctor and patient.

17 That the best possible standard of service be required of the professions and that the remuneration of the professions be consistent therewith.

18 That provision be made for clinical teaching material for medical schools that facilities be provided for research work and that time be allowed for postgraduate work.

19 That the plan be actuarially studied and approved before being adopted, and actuarially checked at periodic intervals.

20 That some plan be devised for the provision of pensions for medical practitioners.

MEDICAL OUTLOOK IN AUSTRALIA

That the war and peace will bring great changes in the organization of medical services in Australia was emphasized by Dr W F Simmons in his presidential address at the annual meeting of the New South Wales Branch of the British Medical Association. While conceding the inevitability of such changes, he questioned whether they constituted the best approach to the problem of medical care.

"Are we not, however, approaching the whole problem from the wrong angle? Has our social legislation advanced so far that the provision of a medical service is the last link in a complete chain of national regeneration?"

"Is it not more necessary to provide adequate and decent homes, the right food, good working conditions, a reasonable wage and sufficient recreational and educational facilities, which combined would diminish the sickness incidence greatly rather than provide a complete medical service to treat and if possible cure diseases which are the result of lack of any or all of these deencies of life?"

If these problems were honestly tackled by any government and if the question of preventive medicine received reasonable consideration at the hands of our political leaders, then I feel that there would be a wonderful opportunity for the profession to cooperate in producing a service which would be in the best interests of Australia and worthy of the men and women providing it.

If, however, these conditions seem too ideal, what are the alternatives? Briefly, the possibilities are as follows:

"1 Medical practice will continue as at present

"2 The profession will be nationalized, I mean thereby that most members of the profession will be salaried officers of the state (compare teachers of the Education Department) but medical practitioners will still be allowed to carry on private practice if they so desire.

"3 A form of national insurance will be introduced based on a contributory system of payment such as has been introduced in New Zealand. Such a system would provide only a general practitioner service, and specialists' services would be provided by private practitioners, by hospitals or by a combination of the two.

"4 A complete system of national insurance on a contributory basis will provide a complete medical service, the general practitioner being paid on a per capita basis and the specialist from a pool.

"5 A system will be created whereby a great part of medical practice is carried on by medical practitioners paid on a salaried basis but still retaining the right of private practice.

Presidential address of W F Simmons read at the annual meeting of the New South Wales Branch of the British Medical Association on March 26 1941. *M J Australia* 1:483 (April 25) 1942.

"6 A scheme of voluntary insurance will be drawn up by the profession itself."

Nationalization of medical service has already been proposed. Concerning this alternative, Dr Simmons says "The public would be regimented. There would be no free choice of doctor. The family physician, who has been guide, philosopher and friend to countless thousands, would be replaced probably by a good doctor, but he would remain the servant of a large department with no choice as to the area in which he worked or to the length of time in which he remained in any one area. Promotion would be slow, and the larger part of a practitioner's professional life would be over before he became a senior."

The speaker seemed to favor the sixth alternative.

"The provision of a voluntary insurance by the profession itself is by no means new. In 1911 the late Dr F Antill Pockley then a leader in association matters, put before this branch his scheme for a voluntary medical service. The premium rate depended on the class of service required. This service was for those ineligible for friendly society benefit on account of their higher income. The premium rate was from five to ten pounds per annum according to the service required. In the last postwar period the parent body put forward its scheme for a public medical service for those whose income exceeded that of the National Health Insurance Act and also for those who were excluded from its benefit for other reasons. Where properly organized, these services are supplying a public need and are growing in popularity. The schemes put forward in our own state by the practitioners at Scone and Canberra have not been able to develop as we should like to see them develop on account of war conditions."

CALIFORNIA BASIC SCIENCE ACT DEFEATED

By a vote of 618,908 against to 385,444 in favor, the Basic Science Initiative, sponsored by the California Medical Association was defeated at the election on November 3. Only four counties gave a favorable vote, of these San Francisco County gave the largest affirmative majority. Nearly \$60,000 was expended by the California Medical Association in preparation of the act securing signatures and in efforts to educate the voters to its desirability. The cultists and quacks of which California seems to have more than its share, conducted a vicious "smear" campaign. Some of the advertisements consisted of personal attacks on Dr Ray Lyman Wilbur, who for some reason was selected as the target for abuse, and might serve as examples for Goebbels in their lack of veracity and violence of language.

WOMAN'S AUXILIARY

Iowa

Members of the Polk County auxiliary have served as hostesses at the USO in Des Moines on the first and third Wednesdays of each month since last April. Ten members furnish the refreshments and four serve them.

New Jersey

The Woman's Auxiliary to the Essex County Medical Society has collected 7,500 pounds of wool clippings worth about \$700. This work is being carried on in cooperation with the Newark chapter of the American Red Cross.

The auxiliary is also furnishing a recreation room and living room for the doctors and nurses on the staff of Camp Kilmer Hospital.

Three emergency medical field sets valued at \$330 were contributed by the Woman's Auxiliary to the Bergen County Medical Society to the Medical and Surgical Relief Committee of America and consigned to the Hackensack Hospital, the Englewood Hospital and the Holy Name Hospital at Teaneck. One

emergency medical field set was contributed by the auxiliary to the Middlesex County Medical Society to the Medical and Surgical Relief Committee of America and consigned to the Naval Supply Depot in Bayonne.

Texas

The Harris County auxiliary entertained, September 15, at River Oaks Country Club, Houston honoring Mrs Peyton R Denman president of the state auxiliary, and Mrs M L Graves, honorary life president of the state auxiliary. Mrs William Lapat and her daughter provided the musical program. About 150 members and guests attended.

The Thirteenth (northwest Texas) District auxiliary met, September 15, at Fort Worth, with representatives from five counties in the district present. Dr H M Williams, acting health officer of Fort Worth and vice chairman of the Emergency Civilian Defense, spoke on civilian defense. Mrs Horace Kibbie of Fort Worth spoke on the 'Place of the Auxiliary During the World Conflict'.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ALABAMA

Changes in Health Officers—Dr John L. Dorrough, Bufalo Cove, N. C., has been elected health officer of Cleburne with headquarters in Heflin.—Dr Garland L. Weidner, Elba, health officer of Coffee County, is now also in charge of Geneva County.

CALIFORNIA

Expansion of Sterilization Program Recommended—At a conference of sixteen state institutions in Sacramento on November 12, it was recommended that the state's sterilization program be expanded to include persons found by courts to be sexually psychopaths and psychopathic delinquents. Extension of the program as recommended would require additional and specific legislation according to Dr Fred O. Butler Eldridge, acting director of state institutions. Newspaper reports pointed out that the existing law governing state insane asylums and homes for the feebleminded provides for sterilization by the state for persons adjudged by the courts to be feebleminded or afflicted with certain types of insanity.

High School Students Eligible for College Training Before Acceptance in Military Service—The board of trustees of Stanford University has voted to accept as first year students beginning with the opening of the winter quarter on January 5 a limited number of highly competent students who have qualified for the senior year in high school. According to *Science*, this plan will permit boys and girls 16 and 17 years of age to have at least one year of college life and work before being called to military service and will give the university an earlier opportunity to secure for the military and other war services young people qualified in such technical fields as medicine, engineering, chemistry, physics, mathematics, military science, industrial management, bacteriology, nursing, geology, mining, foreign languages, government, economics and nutrition. All curriculums will be coordinated with the needs of the Army, Navy and other governmental services and particularly with the requirements of the postwar world it was stated.

DISTRICT OF COLUMBIA

Latin American Radiologist on Tour—Dr Leonardo Guzman, director of the Chilean National Radium Institute of Santiago, Chile and formerly minister of public education, minister of the interior and director general of health arrived in Washington on November 25 for a two months visit to leading cancer research and x-ray centers in this country as a guest of the Department of State. Well known in South America as a cancer specialist, Dr Guzman will observe recent developments in the field of cancer research and treatment in several research centers in the United States. Included among his published works are the *History of the Progress of Surgery During the Past Hundred Years* and *The Life of the Curies*.

ILLINOIS

Concentrated Program for Patients with General Paralysis—The state department of public health and the state department of public welfare have made arrangements whereby patients in danger of developing the symptoms of general paralysis will be given a two to three weeks' course of fever therapy in the state mental hospitals, according to the *Welfare Bulletin*. The nine state mental hospitals located at Chicago, Elgin, Manteno, Kankakee, Peoria, Jacksonville, Alton, Anna and East Moline have set aside sufficient beds and personnel so that these patients can be given a minimum of twelve "fevers" of several hours' duration, with a temperature of 103 F or higher. The treatment takes two to three weeks, depending on the rapidity with which enough high "fevers" are secured. As far as possible, the nonpsychotic patients entering the state hospitals for this purpose will be segregated from regularly committed psychotic patients. The patients will be received by the nine mental hospitals without voluntary or involuntary commitment papers provided they have been properly certified

as being appropriate patients for this type of treatment by the designated health officer of the state department of health. Physicians and clinics wishing to refer patients to the state hospitals for fever therapy to prevent general paralysis should get in touch with any of the following, not with the state hospital but with the health officer of the designated area.

Chicago State Hospital (Dunning), Dr Edward A. Piszczek, health officer of Cook County.
Elgin State Hospital, Dr Felix A. Tornabene.
Chicago East Moline State Hospital, Dr Cornelius E. Kline.
Moline Peoria State Hospital, Dr Sander Horwitz.
1st Peoria Manteno State Hospital, Dr Abraham J. Levy.
Gilman Kankakee State Hospital, Dr Levy.
Jacksonville State Hospital, Dr Frank L. McCord.
Alton State Hospital, Dr Norman J. Rose.
Hickland Anna State Hospital, Dr Roy W. Herrell.
Carbondale.

The *Welfare Bulletin* points out that this fever therapy program should prove a valuable addition to the welfare department's program of preventing the unnecessary long time custodial care of patients in institutions through the execution of active preventive and therapeutic procedures.

Chicago

Officers of Institute of Medicine—Dr Ludwig Hektoen was chosen honorary chairman of the board of governors of the Institute of Medicine of Chicago at its annual meeting December 10. Dr William F. Petersen was chosen chairman of the board. Other officers are Frederick B. Noyes, DDS, president, Drs Clifford G. Grulic, vice president, George H. Coleman, secretary and Grant H. King, treasurer.

Dr Caldwell Resigns as Executive Secretary of Hospital Association—Dr Bert I. Caldwell for fifteen years executive secretary of the American Hospital Association, has resigned effective on the appointment of a successor. Dr Caldwell has also been editor of the association's publication *Hospitals* since its establishment seven years ago. Dr Caldwell graduated at Barnes Medical College, St. Louis, in 1898.

New Psychiatric Training at Illinois Institute—The Illinois Neuropsychiatric Institute recently started a twelve week affiliate course in psychiatric and neurologic nursing. This is the first group of student nurses ever to have classes and clinical experience on the Chicago campus of the University of Illinois. The first school to send students was the School of Nursing of the Presbyterian Hospital. The state is at present providing instruction and experience in psychiatric nursing at both the State School of Psychiatric Nursing functioning at Chicago State Hospital and the School of Nursing at Peoria State Hospital, Peoria. The new affiliate course is intended to augment the already existing facilities of the state in this field. The neuropsychiatric institute was dedicated on June 6, 1942 (*THE JOURNAL*, June 6, p. 506) and is under the joint supervision of the Illinois Department of Public Welfare and the University of Illinois. Its purpose is teaching and research in the field of nervous, mental and behavior disorders.

Physicist Named Head of Parnly Foundation—Peter J. Mills, M.S., head of the department of physics and of mathematics at Thornton Junior College, Harvey, Ill., has been appointed director of the Parnly Foundation for Auditory Research. Mr. Mills graduated at the University of Chicago. An advisory committee has been appointed comprising the following: Dr John S. Coulter, associate professor and in charge of the department of physical therapy, Northwestern University Medical School, Howard Carter, B.S. in M.E., secretary of the Council on Physical Therapy, American Medical Association, Haldon A. Leedy, Ph.D., and Donald E. Richardson, M.S., physicist, Armour Research Foundation, Jesse E. Hobson, Ph.D., director, and Paul G. Andrews, E.E., professor of the Illinois Institute of Technology electrical engineering department, James S. Thompson, Ph.D., director, and Paul L. Copeland, Ph.D., professor, department of physics at the institute of technology. Dr. Mills will serve as chairman of the advisory committee. The foundation which was just established this fall (*THE JOURNAL*, November 7, p. 774) will seek to solve problems of hearing through research. Regarding hearing difficulties as a biophysics problem, the Parnly Foundation will concentrate its work on the physics of hearing. Additional appointments to the advisory committee particularly from the medical field, will be made by the foundation so that cooperation with the medical profession in regard to other aspects of the field may be obtained. The Parnly Foundation is located in the physics building on the south campus of the Illinois Institute of Technology, 3323 Federal Street.

INDIANA

First Presentation of Oberlin Award—In recognition of exceptional services to public health in past years, the Lake County Medical Society at its annual meeting in Hammond December 11, made the first annual presentation of the Oberlin Award to four laymen. The award was created this year in memory of the late Dr. Thomas W. Oberlin, Hammond, one of the society's charter members. The four recipients were H. B. Snyder, editor of the *Gary Post-Tribune*, Sidmon McHie, publisher of the *Hammond Times*, Frank L. Hoess, Hammond, for services nominally credited to him in 1939 and, posthumously, William P. Gleason, former general superintendent of Gary works, who was instrumental in building the James O. Parramore Hospital Crown Point, for services in the years from 1918 through 1936. This marked the first presentation of the award, which in the future will be made annually to but one or two men, women or institutions not directly associated with the healing arts and only in those years when qualified recipients can be selected. The award is in the form of an engraved silver plaque and is presented by the society (*THE JOURNAL*, August 29, p. 1515) "in recognition of significant contributions to the health and consequent welfare, security and happiness of the people of Lake County."

IOWA

Society News—A panel discussion on the sulfonamides was held before the Polk County Medical Society in Des Moines, December 16, under the direction of Dr. Daniel J. Glomset, Des Moines. The society was addressed on November 18 by Drs. Ivan N. Ingram and Henry Field Jr., both of Ann Arbor, Mich., on surgical and medical aspects, respectively, of nontuberculous chest diseases.

Personal—Dr. Herbert M. Huston, Ruthven was honored at a dinner meeting by the Palo Alto County Medical Society in Emmetsburg, October 10, to observe his completion of fifty years in the practice of medicine. Dr. Huston is president of the society.—Dr. Eric P. Pfeiffer, director of the division of vital statistics, Iowa State Department of Health Des Moines has been placed on leave in order to return to active duty in the Army.—Dr. Earl L. Kingsbury Keokuk was recently elected coroner of Lee County.—Dr. William M. Spear, assistant superintendent of the State Sanatorium at Oakdale has been appointed superintendent to succeed the late Dr. John H. Peck.

KENTUCKY

Society News—Dr. James W. Bruce discussed "The Rh Factor in Erythroblastosis of the Newborn" before the Louisville Medico-Chirurgical Society December 11, and Dr. Harry S. Frazier presented a case report on "Streptococcus Viridans Septicemia Treated with Sulfadiazine".—The Transylvania Medical Society was addressed in Louisville December 3, by Dr. Earl R. Gernert on "Plamography of the Chest."

New Health Center—Ground was broken on November 30 for the new Louisville and Jefferson County Health Center. The speakers included Mayor Wilson W. Wyatt and Dr. Arthur T. McCormack, state health commissioner. Federal funds will be used to finance the new unit, which, when completed, will cost about \$100,000. The center will adjoin the Louisville General Hospital, which is also administered by the department of health, and provide accommodations for health officers who are now housed in five different places. Venereal disease clinics and a general preventive clinic will be included in the building. There will also be a seminar room for the use of the health department staff and for the instruction of medical students in preventive medicine.

Personal—Dr. Edward E. Landis, associate in psychiatry, University of Louisville School of Medicine, Louisville, has been carrying on the work of Dr. William K. Keller, associate professor of psychiatry, who is on a leave of absence from the university to engage in active service in the U. S. Navy.—James A. Kennedy, Ph.D., professor of public health and bacteriology, school of medicine, has been accepted for a course in tropical medicine at Tulane University of Louisiana School of Medicine, New Orleans, beginning January 4. This is one of the new fellowships recently established by the Association of American Medical Colleges under a grant from the John and Mary R. Markle Foundation (*THE JOURNAL*, December 19, p. 1329). On completion of the course on February 27 Dr. Kennedy will return to the University of Louisville School of Medicine.—Dr. John P. Wheeler, La Grange, has been appointed superintendent of the new Warren County Tuberculosis Sanatorium at Bowling Green.—Dr. Frank M. Melton, La Grange, has resigned as health officer of Oldham County.

MICHIGAN

Mobile Dental Unit—A traveling dental office is now being used by the state department of health to prepare 18 and 19 year old youths for military service. The 24 foot trailer has complete dental equipment and x-ray camera and will visit areas where the need is greatest because local dentists are serving in the armed forces. High schools in industrial areas of the state will probably be among the first to be visited by the traveling unit. The Children's Fund of Michigan is conducting a survey in the upper peninsula counties to find areas where need of such services is most serious.

Health for Victory Conference—"The Health for Victory Conference" was held in the Rackham Educational Memorial Building, Detroit December 4-5, under the auspices of the Health Council of Metropolitan Detroit and the Council of Social Agencies cooperating with the Wayne County Council of the American Federation of Labor, the Congress on Industrial Organization and other agencies of metropolitan Detroit. A symposium on "Community Health Needs and Resources" opened the meeting. Dr. William W. Bauer, director of the bureau of health education of the American Medical Association, Chicago addressed the evening session on "Americans Live Longer!" Saturday the program consisted of three panel discussions on the health of children, adult health and the health of the industrial worker. The afternoon session was devoted to a consideration of "Health and Welfare of the Nation at War" and panel discussions on occupational diseases, feeding the family and industrial accidents and their prevention.

NEW YORK

War Medicine and Surgery—A postgraduate course on war medicine and surgery will be given for the Oneida County Medical Society at the Utica State Hospital, Utica, under the auspices of the state medical society and the state department of health. Dr. Foster Kennedy, New York, will deliver the first lecture in the series, January 26 on "Nervous Conditions Associated with Warfare," Dr. Philip D. Wilson, New York, February 2, "General Principles of Treatment of War Injuries," Dr. Forrest O. J. Young, Rochester February 9, "The Care of Soft Tissue Injuries," and Dr. James H. Lade, Albany, February 16, "Epidemiology and Control of Syphilis."

State Committee on Child Care—Miss Elsie M. Bond, assistant secretary and executive secretary of the Welfare Legislation Information Bureau of the State Charities Aid Association, has been appointed chairman of the committee on child care, development and protection of the New York State War Council. Miss Bond will spend about half her time in Albany to organize and direct the work of the new committee. She will continue to serve the State Charities Aid Association in administrative matters and in conducting legislative information. The function of the new committee is to assist the localities in meeting the problems of children arising out of the war.

New York City

Welfare Hospital Now Called Goldwater Hospital—The Welfare Hospital for Chronic Diseases Welfare Island has changed its name to the Goldwater Memorial Hospital in honor of the late Dr. Sigismund S. Goldwater at one time health commissioner of New York.

New Officers of the Academy of Medicine—Dr. Arthur Freeborn Chace was elected president for a two year term of the New York Academy of Medicine, December 3. Other officers elected include Drs. Cornelius P. Rhoads for a three year term as vice president, Robert E. Pound, three year term as secretary, Malcolm Goodridge and Harold R. Mixsell, five year terms as trustees and Kirby Dwight to fill the unexpired term of Dr. Chace as trustee through 1943.

Personal—Dr. Alvan L. Barach and Selig Hecht, Ph.D. received Townsend Harris Medals in recognition of "notable postgraduate attainments" at the sixty-second annual dinner of the Associated Alumni of the College of the City of New York, November 14.—Walter H. Eddy, Ph.D. professor of physiologic chemistry in Teachers College at Columbia University has been appointed chairman of the department of nutrition and related sciences at the New York Institute of Dietetics.

School Authorities Reject Social Hygiene Instruction—The city school authorities rejected on December 11 the recommendation of Health Commissioner Ernest L. Stebbins that instruction in social hygiene be given to high school children, according to the *New York Times*. The recommendation was made because of the 20 per cent rise in venereal

infection among boys and girls 15 to 19 years old, it was stated. The board of superintendents had "carefully considered the plan but had concluded that it was 'inadvisable,'" according to the *Times*.

NORTH CAROLINA

Personal—Dr John A. Lineberry, Kenansville, has been chosen health officer of Harnett County to succeed Dr William B. Hunter Lillington, who has been called into active service.

Director of School Health Coordination—Dr William P. Jacobs, Raleigh, at one time state health officer, has been appointed director of school health coordination in the state board of health. The position is subsidized by the Rockefeller Foundation and is a joint project of the state board of health and the state department of public instruction.

OHIO

World's Fair Exhibit at Cleveland Health Museum—A group of exhibits from the Hall of Man, New York World's Fair, including 'The Transparent Man' are on loan from the American Museum of Health, New York for the duration. The *Bulletin of the Academy of Medicine of Cleveland* states that considerable repairing and in some cases reconstruction is necessary. The first series will be on display after the first of the year. The second anniversary luncheon meeting of the Cleveland museum was addressed November 20 by Dr William W. Peter, formerly medical director of the Navajo Area Indian Service Window Rock, Ariz., on 'Keep the Health Fires Burning.'

New Health Commissioner of Toledo—Dr Earl E. Klemschmidt, since 1938 associate professor and chairman of the department of public health, preventive medicine and bacteriology at Loyola University School of Medicine, Chicago, has been appointed health commissioner of Toledo, succeeding Dr John L. Lavan, who recently resigned to become director of scientific research for the National Foundation of Infantile Paralysis, New York (THE JOURNAL, October 17, p. 546). Dr Klemschmidt graduated at the University of Michigan Medical School, Ann Arbor, in 1930. In the past he has been school physician of the Ann Arbor public schools, instructor in public health and preventive medicine at the University of Michigan Medical School and consultant in health education to the U. S. Office of Education, Washington, D. C.

PENNSYLVANIA

Positions Open in State Health Department—The Pennsylvania Department of Health, Harrisburg, announces the creation of a merit system and forthcoming examinations under the new system in medicine and its application to public health, nursing and public health nursing, dentistry and dental hygiene, sanitary engineering, state laboratories including opportunities in bacteriology, serology, immunology and related fields, nutrition, vital statistics, accounting, business management, and community and milk sanitation. Appointments will be made from lists established as a result of open competitive examinations and appointments may be made from these lists during the next three years or longer. Residence requirements are waived for professional positions. Application forms and detailed information may be secured from Charles B. Frasher, merit system supervisor, Department of Health, Harrisburg.

Philadelphia

Special Lectures—Drs Cornelius P. Rhoads and George T. Pack, New York, will address the College of Physicians of Philadelphia and the county medical society in a special meeting, March 10, on 'Newer Advances in Cancer Research.' Dr Carl F. Schmidt, professor of pharmacology at the University of Pennsylvania School of Medicine, will present the Mary Scott Newbold Lecture before the two societies on April 2. His subject will be 'Some Physiological Problems of Aviation.'

Fifty Years Service Honored—On January 12 the Philadelphia County Medical Society will hold a luncheon meeting to honor its members who have completed fifty years or more in the practice of medicine. Certificates will be presented by the state medical society. Included among those who will be honored are Drs. Alexander H. Davisson, William J. Enders, Alfred Hand, Hugh Hanna, Elizabethtown, Pa., Thomas E. Jones, William McKeage, James Herbert McKee, George D. Morton, Honey Brook, Pa., Henry G. Munson, Samuel J. Ottinger, Francis R. Packard, William Egbert Robertson, Robert Ritchie Saunders, Otho Daniel Schaul, George W. Sholler, Melrose Park, Pa., and Philip Adam E. Traut.

RHODE ISLAND

Volunteer Service at Rhode Island Hospital—About eighty volunteers are giving seven hundred hours of service a week at the Rhode Island Hospital, Providence, and are taking the place of about eighteen paid workers according to the state medical journal. Recently a volunteer department was created at the hospital. Adequate quarters, office space, lounging rooms and rest rooms were equipped and opened at the hospital, and a part time paid executive was employed to set the plan in operation. The department was placed under the director of social service, and the Nurses Aides and Gray Ladies recruited under the American Red Cross but representing two volunteer groups requiring specialized training in the nursing field were left under the direction of the superintendent of nurses. The first week the program was in operation thirty nine volunteers other than Nurses Aides and Gray Ladies worked three hundred and twenty-two hours. The state medical journal says that the youngest volunteers are 15 and 16 year old girls who are assigned to the dietary department to peel fruit, butter bread, fill sugar bags and make sandwiches. The oldest volunteer is a 72 year old man, a retired expert accountant, who works in the credit department.

TEXAS

Annual Spring Clinical Conference Canceled—The fifty-third annual Spring Clinical Conference of the Dallas Southern Medical Society scheduled to be held March 22-25 has been canceled.

District Meeting—The North Texas District Medical Association met at the Adolphus Hotel, Dallas, November 30. Among the speakers were Drs. Chester M. Jones, Boston, on 'Clinical Problems in Hepatic Disease', James H. Means, Boston, 'Disorders Affecting the Portal Circulation', Lawrence S. Fells, Detroit, 'Diagnosis and Management of Acute Pancreatitis', and Roy B. Henline, New York, 'Early Carcinoma of the Prostate'.

Grants for Research—Grants of more than \$12,000 made to the University of Texas at Galveston were recently approved by the board of regents. They include \$3,600 from the Research Laboratories of the National Cancer Association for riboflavin and pantoic acid assays to be done under the supervision of Roger J. Williams, Ph.D., director of the institute of biochemistry at the university and discoverer of pantoic acid; \$1,000 from the Williams-Waterman Fund of the Research Corporation of New York to be devoted to combating dietary diseases; the money to be used by Hugh C. Blodgett, Ph.D., associate professor of psychology, for a study of the effect of thiamine on learning behavior; and \$2,500 from Sharp and Dohme, Inc., for research work in the department of surgery by Dr. Edgar J. Poth, associate professor of surgery.

War Program at University—The University of Texas Medical Branch at Galveston conducted a special war program for its seventieth annual graduation exercises on December 18. Charncey D. Lerke, Ph.D., dean and executive vice president of the university, opened the clinical session with a talk on 'Medical Responsibilities of War.' Other speakers were Dr. Edward H. Carr, Dallas, on 'The Role of Specialist in Military Medicine', Isidor S. Ravdin, Philadelphia, 'A New Era in Military Surgery', Cyrus C. Sturgis, Ann Arbor, Mich., 'Blood and Substitutes in Shock', Franklin G. Ebaugh, Denver, 'Psychiatry and War', and Anton J. Carlson, Chicago, 'Obstacles in the Path of an Optimum Diet.' Dr. Judson L. Taylor, Houston, president of the state medical association, gave the principal address at the graduating exercises in the evening. Guests of honor were Drs. Edward Randall Galveston, professor of therapeutics emeritus, and Seth M. Morris, Lamarque professor of ophthalmology emeritus, who are the two living members from the original faculty of the school.

VIRGINIA

Course in Ophthalmology—The ninth annual postgraduate course in ophthalmology and otolaryngology was held at the University of Virginia Department of Medicine, Charlottesville, December 8-11. Included among the lecturers were Drs. H. Marshall Taylor, Jacksonville, Fla., David E. Staunton, Wishart, Toronto, Canada, George E. Shanbrough, Jr., Chicago, Albert C. Furstenberg, Ann Arbor, Mich., William Gayle Crutchfield, Charlottesville, Francis H. Adler, Philadelphia, George C. Ham, Charlottesville, Raymond L. Pfeiffer, New York, Vincent W. Archer, Charlottesville, Edmund B. Spaeth, Philadelphia, and Grady E. Clay, Atlanta, Ga.

GENERAL

Grocery Award Goes to Dr Elvehjem—Comd A Elvehjem, PhD professor of agricultural chemistry at the University of Wisconsin, Madison, and a member of the Council on Foods and Nutrition of the American Medical Association, was presented on November 19 with the eighth annual award of the Grocery Manufacturers of America during its meeting in New York. The group was formerly known as the Associated Grocery Manufacturers of America.

Medical Women's Association Cancels Meeting—At the midyear board meeting of the American Medical Women's Association in Cincinnati, December 5-6 the plans for the association's annual convention, to be held in San Francisco in June, were canceled because of the war emergency. Instead another board meeting will be held in Chicago, June 5-6 immediately preceding the meeting of the House of Delegates of the American Medical Association. Dr Helen I Ritterman, Cincinnati president of the association, has appointed Dr Beulah Cushman, Chicago, to be chairman of this meeting.

Low Mortality Rate in Congress—A lessening of controversy due to the war and increasing health consciousness are credited by Dr George W. Calver, physician in attendance on congress, for the fact that 1942 probably produced the lowest congressional death rate in at least twenty-eight years. According to a statement in the *Washington Evening Star*, December 10, only three members of the house have died this year and there have been no deaths in the Senate. The normal house death rate has averaged twelve a year. Dr Calver said that the 1942 mortality rate was by far the lowest in the twenty-eight years he has been attending physician.

Special Society Elections—Dr Eldwin R. Witwer, Detroit, was chosen president elect of the Radiological Society of North America at its November meeting in Chicago and Dr Robert S. Stone, San Francisco was installed as president. Drs Alfred L. L. Bell, Brooklyn, Davis Spangler Dallas and Robert A. Arens, Chicago, were elected vice presidents at the meeting and Dr Donald S. Childs, Syracuse, N. Y. was reelected secretary-treasurer. Dr Rogers Deakin, St. Louis, was elected president of the American Neisserian Medical Society at its eighth annual meeting in Hot Springs, National Park, Ark., October 22. Other officers are Drs Roger W. Barnes, Los Angeles, vice president, Oscar F. Cox, Boston, secretary, and Striford L. Warren, Rochester, N. Y. treasurer.

Infantile Paralysis Committee Chairmen—At the third annual medical meeting of the National Foundation for Infantile Paralysis, held in New York, December 3 the following medical advisory committee chairmen were reelected: Dr Irvin Abell, Louisville, Ky., General Advisory Committee; Commander Thomas M. Rivers, New York, M. C. U. S. Naval Reserve Committee on Virus Research; Lieut. Col. Philip Levin, M. C. U. S. Army, Committee on Treatment and Prevention of After-Effects; Drs Max M. Peet, Ann Arbor, Mich., Committee on Education; Morris Fishbein, Chicago, Editor of *THE JOURNAL*; Committee on Medical Publications; Herman N. Bundesen, Chicago, Committee on Epidemics and Public Health; and Henry R. Viets, Boston, Diagnostic Committee. Dr Viets was reelected a vice chairman of the General Advisory Committee and Dr Fishbein was elected the other vice chairman. Dr Anton J. Carlson, Chicago, was reelected chairman of the executive committee of the Committee on After-Effects.

Red Cross Offers Social Service Scholarships—A program of American Red Cross scholarship aid has been established as one means of increasing the number of qualified medical and psychiatric social workers available for Army and Navy hospitals and medical and psychiatric units. These scholarships will be granted to selected persons interested in training for these fields of social work offering approved curriculums in medical or psychiatric work. Candidates may designate the school of their choice from the approved list. The aid will cover one academic year, two semesters or three quarters. On completion of training, the scholarship student will be expected to fulfill an agreement for two years' employment with the American National Red Cross. Candidates must be between 22 and 40 years of age, must be in good physical health and must have personality qualifications which indicate a likelihood of success in their chosen fields of work. Educational requirements include the successful completion of one academic year of work in an accredited graduate school of social work. The employment agreement of two years assumes that the service will be within the continental limits of the United States unless a student volunteers for Insular or Foreign service. The scholarships provide full tuition and an allowance of \$65 a month for maintenance. Application forms may be obtained by writing to area assistant directors of the Military and Naval Welfare Service, Hospital Service or the

Personnel Training Unit Services to the Armed Forces American Red Cross, National Headquarters, Washington, D. C. Area office addresses are as follows: North Atlantic Area, 300 Fourth Avenue, New York; Eastern Area, 615 North Asaph Street, Alexandria, Va.; Midwestern Area, 1709 Washington Avenue, St. Louis, and the Pacific Area, Civic Auditorium, San Francisco.

Annual Forum on Allergy—The Fifth Annual Forum on Allergy will be held at the Hotel Statler, Cleveland, January 9-10. On Sunday afternoon Dr Arthur F. Coca, Oradell, N. J. will receive the Forum's Gold Medal "for outstanding contribution to clinical allergy" and deliver the third annual Forum Lecture on "A Critical Review of Fundamental Knowledge Concerning Allergic Diseases." Study groups will be conducted by

Dr Theodore L. Squier, Milwaukee, Allergic Manifestations in the Blood.

Dr Theron C. Randolph, Ann Arbor, Mich., Chronic Urticaria.

Dr John P. Henry, Memphis, Tenn., Allergic Headaches.

Dr Samuel J. Levin, Detroit, Eczema in Children.

Dr Harry Hauser, Cleveland, Reading Chest Plates in Patients Who Wheeze.

Dr Ben Z. Rappaport, Chicago, A Clinical Conception of the Mechanism of Allergy.

Dr Herbert J. Rinkel, Kansas City, Mo., Food Allergy.

Dr Charles H. Evermann, St. Louis, Allergic Purpuras.

Dr J. Warrick Thomas, Cleveland, Allergy of the Eye and Conjunctiva.

Dr Karl D. Figley, Toledo, Ohio, Vasomotor Rhinitis in Children.

Dr Stearns S. Bullen, Rochester, N. Y., The Endocrinological Aspects of the Allergic Patient.

Dr Harry L. Huber, Chicago, Air Conditioning for the Allergic Patient.

Dr Ethan Allan Brown, Boston, Bacterial Allergy and Infections in Asthma.

Dr Armand E. Cohen, Louisville, The Diagnosis and Management of Plant Dermatitis.

Dr Harold J. Friedman, Cleveland, The Evaluation of Drugs Used in Treatment of Allergic Coryza.

Dr Ralph Bowen, Houston, Texas, The Prevention of Allergy in Children.

Dr Jonathan Forman, Columbus, Ohio, Nutrition Problems in Allergic Patients.

Dr George E. Rockwell, Cincinnati, Research in a Private Laboratory.

Dr Cecil M. Kohn, Kansas City, Mo., Physical Allergy.

Dr Rudolph M. Hecht, Chicago, Eruptions of the Hands: Their Diagnosis and Management.

Dr French K. Hansel, St. Louis, Treatment of Nasal Allergy: Specific, Nonspecific and Surgical.

Dr W. Ambrose McGee, Richmond, Va., Food Allergy and Food Disagreements.

Dr Samuel M. Feinberg, Chicago, Asthma in Patients Over Forty-Five Years of Age.

Dr Mary E. H. Loveless, New York, The Immunology of the Atopic Reactions.

Dr Homer E. Prince, Houston, Allergy to Fungi.

Dr George L. Wildbott, Detroit, Industrial Allergic Dermatitis.

Dr Hugh A. R. Kuhn, Hammond, Ind., Allergy of the Ear.

Dr Bret Ratner, New York, The Management of Asthma in Children.

Dr Stanley W. Insley, Detroit, Evaluation of the Drugs Used in the Treatment of Asthma.

Dr Leo H. Crip, Pittsburgh, Extrinsic and Intrinsic Allergy—Their Clinical Differences.

Special lectures will be delivered by Drs. Benjamin S. Kline, Cleveland, on "Observations on the Pathology of Allergy"; Milton B. Cohen, Cleveland, "The Dynamic Mechanism of the Allergic Reaction"; Carl A. Dragstedt, Chicago, "Histamine"; Norman C. Wetzel, Cleveland, "Nutritional Disturbances in the Allergic Child"; Louis J. Karnosh, Cleveland, "Psychosomatic Aspects of Allergy"; Roy W. Scott, Cleveland, "Cardiac Asthma and the Heart in Asthma"; and Clarence A. Mills, Cincinnati, "The Influence of Climate on Disease with Special Reference to the Allergic Syndromes."

FOREIGN

Harben Lectures—Jack C. Drummond, D.Sc., scientific adviser to the British Ministry of Food delivered the Harben Lectures for 1942 at the Royal Institute of Public Health and Hygiene, London, October 26-28 on "Problems of Wartime Nutrition."

Personal—Sir H. Harold Scott, London, retired on August 31 from the directorship of the British Bureau of Hygiene and Tropical Diseases, which he has held since 1935. *Science* reports Dr Charles Wilcocks, London, assistant director of the bureau, has become acting director.

Professor Lapicque Arrested—The *British Medical Journal*, October 10, reported the recent arrest of Dr Louis Lapicque, head of the department of physiology and the General Physiological Laboratory at the University of Sorbonne, Paris and the suppression of the *Presse medicale*.

The Chadwick Lectures—Sir Leonard E. Hill, formerly professor of physiology at the University College, London, recently delivered the first lecture in the thirtieth annual series of the Chadwick Public Lectures of the Royal Society of Tropical Medicine. His subject was "The Interrelation of Clothing and Shortage of Fuel in Matters of Health."

State Control of Medical Practice

State control of the medical profession has greatly increased in recent years, as shown particularly by the national health insurance acts, the scope of which has been extended. The question of a free state medical service for all has arisen. It is argued that when a person is ill he should be entitled to all the medical service necessary, general and special, domiciliary and hospital, and that this should be easily obtainable. The present medical service, like all British institutions, is a thing which has simply grown up and been modified as the occasion demanded. It was not based on any fundamental plan or design. Hence even in the sphere of government control several independent agencies take part in medical care—the Ministry of Health, the Board of Education, the Home Office, the Ministry of Pensions, the Ministry of Labor and the General Post Office. There are more than a thousand voluntary hospitals, while the local authorities control between six and seven hundred which do exactly similar work without any coordination between the two groups. In general practice there is the same diversity. National health insurance provides for twenty-two million employed persons whose income is below \$2,000 annually, while the rest of the people either pay privately or if necessitous, obtain medical care through public assistance. There are also special services for maternity and child welfare under the control of the local authorities.

At the annual representative meeting of the British Medical Association, future medical practice was discussed on the basis of a report of the Medical Planning Commission. The president, Sir Beckwith Whitehouse, spoke of "the swing toward state medicine." While recognizing the necessity of a coordinating body and admitting the immense services which the Ministry of Health had contributed to the nation's health he viewed with some apprehension the inroads in recent years on the influence of that traditional link of British medicine the family doctor and his patient. The bond between the Ministry of Health and the various health services administered by local public health authorities was growing, communal services were increasing, and we might one day soon find ourselves members of a coordinated state health service. He was convinced that neither the people of this country nor the bulk of the medical profession desired to become the regimented units of a system of bureaucratic control. He believed that a system of state medical service would be detrimental to the national health and the personal interests of patient and doctor.

The question was debated whether provision of medical care by the government should be for the whole community or for a part only. It was argued that if further extension of national health insurance came about only 10 per cent of the community would remain outside and that to set up an enormous organization for them seemed unnecessary. An amendment for the inclusion of the whole community was rejected by the narrow majority of 94 to 92. But a motion for the establishment of a whole time salaried government service was rejected by the large majority of 177 to 20.

Sturdy individualism is a feature of the British character and many view with horror the conversion of the medical profession into a branch of the civil service, to be controlled by doctrinaires outside it. Sir Ernest Graham Little (dermatologist and member of Parliament) is a prominent example. He holds that British institutions, developed by slow growth and accommodated to long experience, do much better work than any substitutes planned de novo by the hastily collected commissions now sitting. He regards the voluntary hospitals,

as exemplified by our great medical schools, as a precious heritage whose absorption in a state scheme under state management would spell disaster both for the public and for the profession. He points out the great efficiency of the voluntary hospitals, which are free from any government control. They have been centers of medical research, as contrasted with the medical branches of the armed forces, where departures from routine are frowned on.

The Medical Schools After Three Years' War

The bombing of London led to the evacuation of the medical schools on a large scale to safer places. Air attacks on a small scale continue to be made on this country, but the bombing of London has ceased for over a year and the medical schools are returning. In this fourth winter of the war the preclinical subjects are being taught here again, instead of in the provinces, to which they were transferred. But the preclinical schools of the London Hospital and St. Bartholomew's remain at Cambridge and of St. Thomas's at Godalming, a short distance from London where laboratories and classrooms have been constructed. The extent to which the work of the London schools has been disturbed by the war is illustrated by the case of the London Hospital. Apart from the preclinical school at Cambridge, the medical work is now organized at three centers: the hospital itself (416 beds), the annex at Brentwood (542 beds) and the hospital at Enfield (925 beds). When medical students joining they are at once conscripted for the army unless they obtain hospital appointments, which exempts them for three months.

Postgraduate teaching in London continues at the British Postgraduate Medical School. Beside tuition and lectures are favored rather than specific courses. In alternate weeks there are special courses in war medicine and surgery. A limited number of refugee graduates have been accepted to enable them to put in the hospital practice necessary for the taking of British qualifications.

The British Medical Students' Association

At a recent inaugural meeting of the British Medical Students' Association in London seventeen medical schools and hospitals out of twenty six were represented. Most delegates were in favor of the present shortened medical curriculum, owing to the need for speeding up the supply of doctors for the fighting forces. Teaching should be maintained at the highest level, and to this end the following were recommended: 1. Planned reservation (against conscription) of teachers in all medical schools and greater use of women in teaching posts. 2. The fullest possible use of all available hospital material in the vicinity of each medical school. This must involve the use of municipal hospitals. 3. Immediate consultation between staff and students in each medical school to discuss administrative and teaching difficulties raised by the shortening of the medical course consequent on the war. 4. The setting up of "efficiency committees" in hospitals, covering lay and medical staffs and students. These committees should consider how to improve the organization of hospitals in view of the shortage of hospital staff and pressure of work due to war conditions. 5. The admission of women to all medical schools on equal terms with men. In view of the importance of intensifying the training of medical students, in no case should clinical students undertake any form of national service. The service required of preclinicals should bear immediate relation to their use in cases of emergency. Hence long periods of infantry training were condemned.

Another subject considered was student health. In Edinburgh a special ward is set aside for all students (not medical students alone) in which they receive free hospital care, a special students' insurance scheme has also been established. Students can register with one of five physicians on paying a fee of \$2 per annum, for which they become entitled to free attendance.

New Steps to Combat Tuberculosis

Speaking at the opening of a sanatorium built at a cost of \$800,000 by the Nottingham Corporation, the minister of health, Mr. Ernest Brown, described the new steps by the ministry to combat tuberculosis. Soon they would put into practice the principle that success depended on treatment in the early stages, if possible before any symptoms were noticed by the person attacked. They had ordered sets of miniature radiography apparatus for this purpose, which would be ready by the end of the year. Ideally every one ought to undergo a regular examination. The minister said that we had in England and Wales more than 27,000 beds for the treatment of tuberculosis. Those beds were served by 5,200 nurses and nursing auxiliaries and 4,800 domestic workers. Some beds for tuberculosis had been released from the Emergency Hospital Scheme (established for the treatment of the civilian casualties of the war), but to bring them into use twelve hundred nurses and nine hundred more domestic workers were required.

Malaria Discussed at Pan American Sanitary Conference

The eleventh Pan American Sanitary Conference was held in Rio de Janeiro from the 7th to the 18th of September. The present situation of malaria in the Western Hemisphere was presented by Dr. Arnoldo Gibaldon, delegate from Venezuela, and Dr. Mark F. Boyd, delegate from the United States, the former as president of the permanent committee on malaria of the Pan American Sanitary Bureau and the latter as president of the subcommittee on malaria surveys. Malaria, the report states, is already considered a major public health problem in the majority of the American republics. The disease is not present in Uruguay, according to the information of Dr. Schiaffino, director of the National Health Department, and is of a limited importance in Chile, where malaria prevails in a small area of the extreme north of the country. In the sixteen republics from which the committee was able to gather information, the malaria control work is a direct and exclusive function of the National Departments of Health in ten nations (Argentina, Bolivia, Costa Rica, Cuba, Dominican Republic, Guatemala, Haiti, Mexico, Paraguay and Peru), while in three (Brazil, Colombia and Ecuador) it is carried out by cooperation between the national and the state departments of health, and in two (Salvador and Venezuela) this cooperation involves also the counties. The place the malaria organization has in the general scheme of government varies considerably in the different American countries, but in the most frequent case (Argentina, Brazil, Costa Rica, Cuba, Dominican Republic, Guatemala, Haiti, Peru, Salvador and Venezuela) it is one of the main administrative divisions of the National Health Department. In two countries (Bolivia and Mexico) the malaria bureau is only a part of one of the main divisions of the department, while in two others the work is carried out by a special section of the division of sanitation, and in Paraguay it depends on the cooperation of the divisions of epidemiology, hygiene and rural sanitation. The report points out that several countries of the Western Hemisphere have already reached significant progress in relation to the development of a satisfactory malaria control organization. A table was presented showing the appropriations for the malaria control work in the last three years expressed in American dollars. For the year 1941, for instance, the appropriations vary from the minimum of \$10,000 in the Dominican Republic to \$100,600 in Cuba, \$104,200 in Peru, \$155,200 in Mexico, \$305,700 in Argentina, \$384,100 in Venezuela and \$416,000 in Brazil. It is gratifying to observe that the malaria control work is being carried out with increas-

ing emphasis, as is demonstrated by the rise in the total of the appropriations for the last three years from \$701,600 for 1939 to \$1,711,400 for 1941.

The technical personnel, divided into malarialogists, entomologists and sanitary engineers, is generally considered insufficient in number and needing a more complete specialization. The report stresses the necessity for physicians having more specialization in malarialogy, the entomologists more specialization in taxonomy and in the use of larvicides, and the engineers in the theory and practice of the minor works of malaria sanitation. In this respect the health departments of thirteen nations (Argentina, Brazil, Colombia, Costa Rica, Cuba, the Dominican Republic, Ecuador, Guatemala, Haiti, Mexico, Peru, Salvador and Venezuela) have informed the committee that they have one or more specialists classified as malarialogists: seven of the nations have only one, five have from two to ten, and one nation (Brazil) has thirty-four. The specialists in entomology are much more abundant. All these thirteen republics have sanitary engineers in the malaria control organizations except Colombia, which reports that the work is done by engineers of other divisions of the health department.

The sixteen nations to which the report refers have carried out more or less complete studies about the anophelines of their areas. In only a few of the countries in the subtropical zone is the anopheline fauna sufficiently known. Another phase of this subject is the determination of the species responsible for the transmission of the disease. In some nations this will have to wait for the final solution of some intricate problems of taxonomy. In almost all the Caribbean Sea countries the importance of *Anopheles albimanus* is indisputable. Between this region and Argentina *Anopheles pseudopunctipennis* is definitely incriminated. The importance of this species is probably much greater than is indicated by this enumeration, but it may be obscured by certain yet unknown points of the racial composition of the species. All the available data indicate the complexity of the problem of vectors in the nations east of the Andes, and the nature of this problem is known only in part. At least in Argentina and in Brazil, for example, *Anopheles albimanus* is still an unsolved question. *Anopheles darlingi*, perhaps the most dangerous vector indigenous to the Americas, represents a well recognized problem in Brazil, Venezuela and Guatemala, and later it will probably be incriminated in some other areas. *Anopheles tarsimaculatus* var. *oswaldi* has been considered to be another vector of some importance in Brazil, which had to face the problem of *Anopheles gambiae*, imported from Africa through air transportation and the eradication of which constituted a paramount sanitary achievement already reported in *THE JOURNAL* (Dec. 27, 1941, p. 2267). The report recognizes that the neighboring countries, and even the most distant nations in the Western Hemisphere, have contracted a debt to Brazil for this great achievement, which proved the technical ability and the perseverance of the health authorities of the nation.

Marriages

RAYMOND J. MCGANN, Mount Sterling, Ill., to Miss Mary Agnes Gray of St. Joseph, Mo., recently.

JOHN WOOTEN MEREDITH, Scottsville, Ky., to Miss Raechel Nadine Holland at Bardstown, June 14.

CLARENCE WILSON ORR to Miss Mary Elizabeth Holler, both of Spartanburg, S. C., June 14.

DAVID J. TSCHETTER, Canton, Ohio, to Miss Ursula Mary Burns of Chicago, September 21.

ARTHUR J. KATZBERG, Baltimore, to Miss Mae Wier at Washington, D. C., July 1.

WALTER LYON BLOOM, New York, to Miss Suzanne Ferst of Atlanta, Ga., recently.

Deaths

Sherman Grant Bonney, Denver, Harvard Medical School, Boston, 1889, member of the House of Delegates of the American Medical Association in 1902, member of the Colorado State Medical Society at one time dean and professor of medicine at the Denver and Gross College of Medicine, professor of medicine emeritus and formerly professor of diseases of the chest at the University of Colorado School of Medicine, fellow of the American College of Physicians, member of the American Clinical and Climatological Association, past president of the Denver Clinical and Pathological Society, at one time a director of the National Association for the Study and Prevention of Tuberculosis, formerly on the staffs of St Luke's and St Joseph hospitals, author of *Pulmonary Tuberculosis and Its Complications* first edition published in 1908 and second edition in 1910, aged 78, died November 19, of heart disease.

Harry Clyde Hoffman ♂ Connellsville, Pa. University of the Pennsylvania Department of Medicine, Philadelphia, 1905, past president of the Fayette County Medical Society at one time on the staff of the Somerset (Pa.) Community Hospital and superintendent of the Somerset County Home and Hospital, Somerset, member of the surgical staff of the Connellsville State Hospital from 1912 to 1937, a trustee of the Gettysburg College from 1920 to 1937, formerly a member of the Gettysburg Theological Seminary board, aged 65, died, November 11, in Barnesville, Ohio, of carcinoma of the pancreas.

Grace Niebuhr Kimball, Poughkeepsie, N. Y. Woman's Medical College of the New York Infirmary for Women and Children, New York, 1892, member of the Medical Society of the State of New York, for many years a medical missionary in Turkey, past president of the Medical Woman's National Association, at one time assistant physician at Vassar College, formerly member of the city board of health, president of the board of trustees of the Samuel W. Bowne Memorial Hospital from 1911 to 1941, aged 87, died, November 18, of heart disease.

William Otis Faxon ♂ Stoughton, Mass. Boston University School of Medicine, 1876, served in the Massachusetts House of Representatives in 1905-1906 and as state senator in 1907-1908, medical examiner of Norfolk County for more than forty years, chairman of the examining board during World War I, in 1939 received the honorary degree of doctor of science from Boston University, aged 89, died November 12, in the Massachusetts General Hospital, Baker Memorial, Boston, of subdural hemorrhage.

Arthur J. Anderson ♂ Lawrence, Kan. Hahnemann Medical College and Hospital, Chicago, 1887, past president of the Kansas State Board of Medical Registration and Examination at one time associated with the Indian Service for thirty five years, school physician of Lawrence in 1936 was presented with a silver plaque by the Douglas County Medical Society in celebration of his completion of fifty years in the practice of medicine, was a past president of the society, aged 79, died, October 8.

Erastus Corning, Albany, N. Y., Albany Medical College, 1907, member of the Medical Society of the State of New York, adjutant and later commanding officer of a unit of Base Hospital number 33 in France during World War I, was promoted to lieutenant colonel and went to Archangel, Russia, as surgeon in chief of the Russian expeditionary forces, aged 63, on the staffs of the Memorial Hospital and St. Peter's Hospital, where he died, November 11, of bronchopneumonia and diabetes mellitus.

Ralph Emerson Weible ♂ Fargo, N. D. Rush Medical College, Chicago, 1901, member of the founders' group and specialist certified by the American Board of Surgery, past president of the Cass County Medical Society, fellow of the American College of Surgeons, one of the founders and president of the Dakota Clinic, recently a member of the medical advisory board of the Selective Service System, surgeon, St. John's Hospital, aged 63, died, November 8, in Minneapolis.

George Eyerman McLaughlin, Brooklyn, University of the City of New York Medical Department, New York, 1891, at one time member of the board of health of Jersey City, formerly on the staffs of the Christ Hospital (Jersey City) and the Bayonne (N. J.) Hospital, served as a U. S. Navy surgeon with the rank of lieutenant commander during World War I, aged 73, died, November 8, in the Long Island College Hospital of arteriosclerotic heart disease.

Lewis Leroy Bartlett, Dalhart, Texas, State University of Iowa College of Medicine, Iowa City, 1895, served the Dallam-Hartley-Sherman-Moore Counties Medical Society as

president in 1930, health officer of Dallam County from 1918 to 1922, formerly member of the city council of Dalhart and the board of education, aged 81, died, September 24, of arteriosclerotic heart disease.

Charles Edward Roderick, Dayton, Ohio, Medico-Chirurgical College of Philadelphia, 1914, member of the West Virginia State Medical Association and of the American Society of Clinical Pathologists, pathologist on the staff of St. Elizabeth Hospital, aged 52, died, November 6, in the Stillwater Sanatorium of tuberculous meningitis, enteritis, portal cirrhosis and arteriosclerosis.

E. Wood Ruggles ♂ Rochester, N. Y., College of Physicians and Surgeons, New York, 1888, an Affiliate Fellow of the American Medical Association, member of the American Dermatological Association and the American Urological Association, past president of the Monroe County Medical Society and of the Rochester Pathological Society, aged 81, died, November 7.

John Paultett Clark, Lynchburg, Va., University of Virginia Department of Medicine, Charlottesville, 1896, member of the Medical Society of Virginia, for many years public school physician on the visiting staff of the Lynchburg General, Virginia Baptist and the Memorial hospitals, aged 72, died, November 9, of carcinoma of the prostate.

Jesse Austin Spence, Mansfield, Ohio, Miami Medical College, Cincinnati, 1887, member of the Ohio State Medical Association, for many years medical examiner for the Pennsylvania Railroad, member of the library board, formerly member of the school board, aged 82, died, November 11, in the Mansfield General Hospital of heart disease.

John Sims Crutcher Sr. ♂ Athens, Ala. University of Nashville (Tenn.) Medical Department, 1889, Vanderbilt University School of Medicine, Nashville, Tenn., 1889, formerly served as health officer of Limestone County, on the staff of the Limestone County Hospital, aged 77, died, November 6, in the Vanderbilt Hospital, Nashville.

James Keel Coddington ♂ Humboldt, Iowa, State University of Iowa College of Homoeopathic Medicine, Iowa City, 1900, past president and secretary of the Humboldt County Medical Society, for many years county coroner, aged 70, died, November 4, in the Lutheran Hospital, Fort Dodge, of coronary thrombosis.

Louis M. Brown, St. Petersburg, Fla. University of Pittsburgh School of Medicine, 1909, member of the Medical Society of the State of Pennsylvania, medical director of the Allegheny County Home and Hospital for the Insane, Woodville, Pa., from 1930 to 1937, aged 63, died, November 5, of cerebral thrombosis.

Harry H. Heylman ♂ Long Beach, Calif., Kansas City (Mo.) Medical College, 1897, specialist certified by the American Board of Radiology, Inc., member of the Radiological Society of North America, Inc., and the American College of Radiology, aged 75, died, October 30, in the Seaside Hospital of aortic aneurysm.

Clifford Ray Hoy ♂ Syracuse, Ind., Indiana University School of Medicine, Indianapolis, 1913, served overseas as a captain in the Evacuation Field Hospital number 9 both in France and in Germany during World War I, aged 54, died, November 7, in the Elkhart (Ind.) General Hospital of a subphrenic abscess.

John Daniel Fouts, Dayton, Ohio, Ohio Miami Medical College, Cincinnati, 1910, member of the Ohio State Medical Association and the American Academy of Ophthalmology and Otolaryngology, aged 56, on the staff of the Miami Valley Hospital where he died, November 10, of cerebral hemorrhage and hypertension.

Arthur Corliss Liston, Bellows Falls, Vt., Baltimore Medical College, 1906, member of the Vermont State Medical Society, served during World War I, appointed roentgenologist at the Rockingham General Hospital in 1939, aged 58, died, November 10, of carcinoma of the bladder.

Joseph Livingston Fewsmith ♂ Newark, N. J., Columbia University College of Physicians and Surgeons, New York, 1902, on the staffs of St. Michael's Hospital, Presbyterian Hospital and the Hospital of St. Barnabas and for Women and Children, aged 65, died, November 2, of coronary thrombosis.

Samuel Archie Joslyn ♂ Loveland, Colo., Denver and Gross College of Medicine, Denver, 1904, past president of the Larimer County Medical Society, formerly on the staff of the Loveland Hospital and Clinic, chief of staff, Nanuet Hospital, aged 61, died, October 8, of coronary thrombosis.

Henry Osgood Anderson, Williamsport, Tenn, University of Nashville Medical Department, 1907, member of the Tennessee State Medical Association, past president of the Maury County Medical Society, served during World War I, aged 62, died, November 16, in Nashville of heart disease

Charles Martin Alt, Baltimore, Ohio, Stirling Medical College, Columbus, Ohio, 1895, member of the Ohio State Medical Association in 1940 received a plaque from the Fairfield County Medical Society for having practiced more than forty years, aged 73, died, October 21, in Lancaster

Jesse G. Hilton, Menard, Ark., American Medical College, St. Louis, 1905, member of the Arkansas Medical Society secretary and past president of the Polk County Medical Society, aged 68, died, November 8, in a hospital at Hot Springs National Park of carcinoma of the pancreas

Walter Clark Crombie, East Orange, N. J., Albany (N. Y.) Medical College, 1879, member of the Medical Society of the State of New York, for many years a member of the board of education in Mechanville, N. Y., aged 87, died, November 24, of uremia and myocarditis

William Roy Hedrick, Decatur, Ill., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910, member of the Illinois State Medical Society, for many years county physician, aged 56, died suddenly, November 17, of coronary thrombosis

Benjamin Clayton Arnold & Jackson, Penn., Vanderbilt University School of Medicine, Nashville, 1913, served as a captain in the medical corps of the U. S. Army during World War I, aged 53, died, November 13, in the Webb Williamson Hospital of cerebral hemorrhage

Ed N. Loy, Rensselaer, Ind., Chicago Homeopathic Medical College, 1898, served as examining physician during World War I, health officer of Rensselaer, aged 70, died, November 14, of coronary occlusion, cardiovascular renal syndrome and transverse myelitis

Charles Lansing Witbeck & Colloes, N. Y., Albany Medical College, 1901, police and fire department surgeon, coroner's physician in 1909, at one time on the staff of the Colloes Hospital, aged 67, died, November 4, in Maplewood, N. J., of cardiac insufficiency

Arthur Wrigley & Philadelphia, Medico-Chirurgical College of Philadelphia, 1901, at one time a member of the board of health of Philadelphia, for many years senior chief of the ear, nose and throat service at St. Joseph's Hospital, aged 65, died, November 4

Robert French Mason, Washington, D. C., University of Maryland School of Medicine, Baltimore, 1894, formerly gynecologist in charge of the dispensary service at the Garfield Hospital, aged 73, died, October 29, of coronary occlusion and coronary sclerosis

Julius F. Mauermann, Monroe, Wis., Northwestern University Medical School, Chicago, 1903, member of the State Medical Society of Wisconsin, aged 70, died, October 23, in Orangeville, Ill.

Merle Parrish & Kansas City, Kan., University of Kansas School of Medicine, Kansas City, 1928, aged 40, on the staff of the Providence Hospital, St. Margaret's Hospital and the Bethany Hospital, where he died, November 8, of coronary occlusion

William John Francis Martin, Philadelphia, Atlantic Medical College, Baltimore, 1908, member of the Medical Society of the State of Pennsylvania, for many years physician for the city parochial schools, aged 63, died, November 22

Clifford H. Irion, Benton, La., Medical Department of Tulane University of Louisiana, New Orleans, 1884, past president of the state board of health and the school board of Bossier Parish, aged 81, died, November 3, in a hospital at Shreveport

David Henry Monahan, Bridgeport, Conn., Dartmouth Medical School, Hanover, N. H., 1900, at one time member of the board of education and board of health, formerly on the staff of St. Vincent's Hospital, aged 80, died, November 7

John Danner Thomson & Atlanta, Ga., Jefferson Medical College of Philadelphia, 1904, served as a captain in the medical corps of the U. S. Army during World War I, aged 62, died, November 10, of estivo-autumnal malaria and heart disease

Smith Forrest McDonald & Severy, Kan., Kansas Medical College, Medical Department of Washburn College, Topeka, 1903, health officer of Greenwood County, aged 66, died, November 2, in a hospital at Wichita of heart disease

John Rush Warren, Marietta, Ohio, Ohio State University College of Medicine, Columbus, 1917, served during World War I, aged 50, died suddenly, October 15, in the Swan Hospital, Cambridge, of acute dilatation of the heart

David Este Weatherhead, Cincinnati, Medical College of Ohio, Cincinnati, 1898, also a druggist, at one time county physician, aged 67, died, November 4, in the Good Samaritan Hospital of carcinoma of the transverse colon

John S. Wallner & Chicago, Illinois Medical College, Chicago, 1904, aged 67, died, November 5, in the Columbus Hospital of acute cardiac dilatation, chronic myocarditis and coronary artery disease

John W. Ringgold, Ashdown, Ark., Arkansas Industrial University Medical Department, Little Rock, 1890, member of the Arkansas Medical Society, county health officer, aged 71, died, September 8

William Vincent McCready, Providence, R. I., University and Bellevue Hospital Medical College, New York, 1901, aged 68, died, November 2, in New York of chronic pulmonary tuberculosis

Millard Lieser Smith, Dothan, Ala., Tulane University of Louisiana School of Medicine, New Orleans, 1918, aged 49, died, November 8, in the Moody Hospital of chronic myocarditis

James Jefferson Mallard, Royersford, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1922, aged 44, was found dead, November 11, of coronary thrombosis

Charles Eliot Hirsh, Brooklyn, Long Island College Hospital, Brooklyn, 1892, aged 82, died, November 4, in the Methodist Hospital of carcinoma of the lung

Henry S. Schuhmann, Brooklyn, University and Bellevue Hospital Medical College, New York, 1902, aged 66, died, October 15, of cerebral thrombosis

Jacob Lichtenstein, New York, Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1894, aged 72, died recently of heart disease

Richard Mayer, Oakland, Calif., Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1929, aged 39, died, September 3

Ella M. Bergtold, Bowmansville, N. Y., University of Buffalo School of Medicine, 1918, aged 58, died, November 17, in Buffalo of hemiplegia

Hermann Julius Schirmer, Guttenberg, Iowa, College of Physicians and Surgeons, New York, 1882, aged 85, died, October 16, of senility

Wright Sylvester Mims, Ardmore, Tenn., Memphis Hospital Medical College, 1910, aged 65, died, November 9, of acute myocarditis

Thomas V. Hammond, Berlin, Md., Jefferson Medical College of Philadelphia, 1882, aged 81, died, November 11, of paralysis agitans

Jerome M. Glaze, Van Nuys, Calif., Vanderbilt University School of Medicine, Nashville, Tenn., 1885, aged 77, died, September 18

Stella Cox Venable, Geneseo, N. Y., University of Buffalo School of Medicine, 1888, aged 84, died, November 5, of chronic endocarditis

Charles A. Kelly, Clarksville, Tenn., Meharry Medical College, Nashville, 1900, also a pharmacist, aged 75, died, October 12

Conrad Joseph Becker & Wilkes-Barre, Pa., Medico-Chirurgical College of Philadelphia, 1906, aged 64, died, September 29

Martin Kramer, Pella, Iowa, Missouri Medical College, St. Louis, 1880, aged 88, died, October 7, in Pleasantville of gangrene

John Huecker, Waukon, Iowa, Denver College of Medicine, 1898, aged 72, died suddenly, November 10, of heart disease

Edward C. Zoll, Elmwood, Ill., Keokuk (Iowa) Medical College, 1898, aged 80, died, November 13, of cerebral thrombosis

Chastine G. Williams, Oak Grove, Va., University College of Medicine, Richmond, 1896, aged 70, died, October 3

John Daniel Estell, Cincinnati, Eclectic Medical Institute, Cincinnati, 1902, aged 66, died recently of chronic nephritis

Ulysses S. G. Beam, Lima, Ohio, Louisville (Ky.) National Medical College, 1895, aged 75, died, October 11

Solomon E. Greenwood, Fletcher, N. C., Tennessee Medical College, Knoxville, 1902, aged 64, died, October 28

James Isaac Bradshaw, Erym, Tenn., Tennessee Medical College, Knoxville, 1901, aged 74, died, October 30

W. H. McWhorter, Burns, Miss., (licensed in Mississippi in 1897), aged 84, died, October 14

Correspondence

CONSERVATION OF PAPER

To the Editor—At the hospital staff meeting we were informed that, owing to pressure from government boards controlling the use of raw materials, certain form sheets used in our case histories will no longer be furnished. For example, "progress" and "follow up" notes will, for the duration, go on the same sheet. This may not be a vital change, but the hospital is making a definite sacrifice. The histories will be less easily digested and abstracted when somebody wishes to tabulate a number of them. Yet if this trifling change can be of the slightest use in the war effort, it has our wholehearted approval.

Here is the rub. After that meeting, I visited my mail box in the hospital and abstracted sixteen pieces of mail that made a mass of paper weighing 1 pound 9 ounces. Many folders consisted of numerous pages, some printed in brilliant colors. Many, many hours of work by able bodied printers had gone into the preparation of that material. And that at a time when the nation is crying for manpower for the war effort. All that printed matter told wondrous tales of this and that certain to transform the practice of medicine into a dream of joy.

We are told that paper is scarce, pigments for colored inks are scarce, the working time of skilled men is scarce. Why then is it permitted to waste these values on the masses of junk that descend into our mail boxes daily? All that stuff I mentioned promptly went into the scrap basket. I know I am tweeking the tail of the Sacred Cow of advertising, for that profanity I will lose caste with the pundits. I would sooner lose caste than lose this war. Cannot we physicians do something to discourage the horrible waste represented by the masses of printed matter that flood us? Do not patronize the wastrels.

JOSEPH T. SMITH, M.D., Boston

FOR A BETTER MEANS OF ESTIMATING THE NEED FOR RESTORATION OF THE BLOOD VOLUME

To the Editor—The benefit of infusion of serum in cases of shock seems now to be established beyond all doubt. Particularly after severe burns, if the loss of serum externally is not to induce a development of shock, restoration of the blood volume is imperative. The question then is: How can the surgeon best judge when, how much and how rapidly serum should be administered?

It seems now to be generally accepted that failure of the circulation, or shock from decrease of blood volume, is not due to depression of the vasomotor control of the arteries but that the fall of arterial pressure is secondary to the decrease of the venous return. The heart can pump into the arteries no more than the decreased volume that it receives from the veins.

It would therefore be more logical and afford an earlier and more quantitative index of a failing circulation to measure directly the volume, or decrease of volume, of the venous return than to rely, as at present, almost wholly on measurements of arterial pressure alone. The reason that the venous return is not now measured seems to be that surgeons are generally unaware that there is any method for this purpose.

Yet there is such a method, and it is very simple. It consists in the measurement of the column of blood in the veins of the arm when the patient is tipped up momentarily into an extreme head down and feet up position—a slope of at least 1:4. This is a different matter from the practically worthless figures

for venous pressure when the body is horizontal. Measurements, then, as between health and shock, can differ by only a few millimeters of blood. But when the body is inverted, the venous column varies by many centimeters—a high column indicating a full volume of venous return, and a low column affording a direct indication of the need for infusion of serum or blood (Henderson, Yandell, and Haggard, *H. W. J. Pharmacol. & Exper. Therap.* 11:189 [April] 1918; Henderson, Yandell, *Science* 95:539 [May 29] 1942).

Although the head down and feet up position is not so much of an aid to the circulation as surgeons generally believe, it can be a great aid in diagnosis. For when all the blood returning from the tissues is, by means of inversion of the body, poured into the uncapsulated and relatively undilatable veins of the head and neck, the pressure of blood in those vessels is an index of the volume of the venous return. To measure that pressure, one of the patient's arms is held vertically or lifted gradually, and the height of the column of blood in the veins is measured from some fixed point of reference such as the symphysis of the clavicles. Estimated in this way the volume of the venous return has been found to be greatly decreased after some major surgical operations and also in cases of acute illness. As recovery develops the venous column rises again, as vitality fails, the venous column sinks progressively lower until it reaches zero is the tone of the body's musculature disappears at death.

Such measurements of the venous return give indications of decrease of the active blood volume and the need for infusion of serum or blood much sooner and more significantly than the now conventional measurements of arterial pressure alone.

YANDELL HENDERSON, PH.D., M.D. (HON.),

NEW HAVEN, CONN.

THE PEPPER HEARINGS ON MEDICAL MANPOWER

To the Editor—It is difficult to understand how such a garbled and undited stenographic report of my testimony before the Senate Committee could have been published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*.

In the editorial it was stated that I would be in favor of a totalitarian government if it meant that tuberculosis could be eradicated. Actually I made no mention whatever about our government. Even to suggest that I thought that this wonderful government of ours, for which our boys are fighting and dying, should be changed is absurd and beyond comprehension. In my testimony I was speaking of public health only and stated that I wanted it taken care of and that "whether you call this totalitarianism or industrial medicine or group medicine or American Medical Association, I don't care." In another instance I stated that public health is bigger than individuals and that we must adjust ourselves to that premise. I stated also that our efforts to control it should be continued. Whether this was done in a democratic or totalitarian way made no difference as long as it was done. This could not possibly be construed honestly as meaning that I am for a totalitarian form of government.

Public health vitally interests two widely separated groups—the one the public which is afflicted with disease, and the other the medical profession which is supposed to cure for it. If the latter proves ineffectual in any community or under any circumstances, the public has a right to demand—and get—the proper care. Therefore, a proper allocation of doctors is obviously essential. These are truths which are not debatable.

E. J. O'BRIEN, M.D., Detroit

Council on Medical Education and Hospitals

CONTINUATION COURSES FOR PRACTICING PHYSICIANS

In accordance with the plan of the Council on Medical Education and Hospitals, advance information concerning continuation courses for practicing physicians available in the various centers is published quarterly. The following list con-

sists of courses beginning during the period Jan 1, 1943-March 31, 1943. It is hoped that this material will be useful to physicians seeking opportunities for postgraduate work. Physicians called on to assume new responsibilities because of the war and physicians who are returning to practice may find here listed courses which will be of help to them. Since many of the classes are necessarily limited, those who contemplate enrolling in any of these courses are urged to communicate as early as possible with the proper executive officer.

H G WEISKOTTEN, M D,
Secretary, Council on Medical
Education and Hospitals

Continuation Courses for Practicing Physicians January 1-March 31, 1943

Institution	Schedule of Course	Title of Course	Number of Students Accepted	Registration Fee and/or Tuition
ALLERGY —See also Dermatology & Syphilology Southwest Allergy Forum, Shreveport, La. Write to Dr. Mun Cazorl, Sec 3, 702 Dunakley Bldg., Little Rock, Ark.	March 12-13	Allergy		
Columbia University, Faculty of Medicine at the New York Postgraduate Medical School, 303 East 20th Street, New York, N. Y. Write to Director of the School.	March 29-April 16 ^a	General course	48	\$150 ^a
University of Pennsylvania Graduate School of Medicine, 17 Medical Laboratories Philadelphia, Pa. Write to Dr. R. C. Baerkl, Dean, The Medical-Chirurgical College, Drs. Vaughan and Graham, 201 West Franklin St., Richmond, Va. Write to Dr. Warren F. Vaughan.	Arranged, 4 weeks about 40 hours 1 year course Every 6 months	Allergy Training in allergy	Individuals ² Limited	\$150 L
ANATOMY New York Medical College, Flower and Fifth Avenue Hospitals, 5th Avenue at 10th St., New York, N. Y. Write to Dr. J. A. W. Hetrick, Dean.	Arranged, 60 hours Arranged, 60 hours Arranged, 100 hours Arranged, 90 hours	Applied anatomy of the urogenital system Applied anatomy of ear, nose and throat Surgical anatomy Applied anatomy of pelvis and abdomen		\$150 ¹⁷ \$150 ¹⁷ \$250 \$250
ANESTHESIOLOGY Harvard Medical School, 25 Shattuck Street, Boston, Mass. Write to Dr. Frank R. Ober, Assistant Dean. 1 Physicians who have had adequate preliminary training and/or experience

2 Specialists

3 Limited to applicants approved by the instructor department head etc

4 Male physicians only

5 Physicians licensed to practice in the state

6 Physicians who wish to specialize

7 Members of the organization

8 Officers of the United States Army Navy or Naval Reserves on active duty

9 Medical Reserve Officers of the United States Army

10 Fellows and Junior Candidates of the college

11 A faculty course for staff members of mental institutions

12 Microscope required

13 A temporary license to practice medicine in the state is required

14 A registration fee of \$5 covers all courses taken within the year

15 Plus a laboratory fee

16 Plus a matriculation fee and/or incidental fee

17 If two or more students register for the course at the same time

18 If taken in conjunction with the next course above/below (Gastros

copy/Peritoneoscopy) the fee for the combined course will be \$125

11 Includes a subscription to the organization's publication

20 No fee for members of the organization

21 No fee for physicians in military service

22 Half fee for physicians in the military service

23 Returned on satisfactory completion of the course

24 Grants may be made from a scholarship fund

25 Per diem and/or maintenance provided

26 A monthly stipend is paid

27 Assistantships internships residencies available

28 Register two to six weeks in advance

29 Repeated

30 Longer courses arranged in units of 12 sessions each

31 Given at separate hospitals for Negro and white physicians

32 Applicants must not be over 36 years of age

33 Plus service in the outpatient department

34 Part of the course may be taken at a reduced fee

35 Physicians recommended by directors of state or city health departments

36 Physicians in the local area

37 Registration fee of \$3 applied on tuition

38 For physicians under 49 years of age

39 \$50 For physicians in armed forces

Missouri Reciprocity Report

The State Board of Health of Missouri reports 18 physicians licensed to practice medicine by reciprocity and 3 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners on Sept 28, 1942. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Arkansas School of Medicine		(1938)	Arkansas
Stanford University School of Medicine		(1941)	California
Howard University College of Medicine		(1939)	Virginia
University of Illinois College of Medicine		(1925)	Kentucky

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts Death from Carcinoma of Testicle Allegedly Accelerated by Industrial Accident—Jensen, after submitting to a "whole physical examination," was employed by a mining company. About four months later, Jan 3 1941, while in the course of his employment, he fell from a saw horse, or from a box placed on a saw horse, striking his right testicle on a piece of coal or on the bar he was using in the mining operation in which he was engaged. On returning home that evening he complained to his wife of pain and exhibited a bruised right testicle. Either that night or the next he was attended by Dr. Long, the company physician, who in his report to the company stated that the worker had a "contusion of the right testicle." Jensen continued his employment until January 14, at which time the pain had become so intense that he was forced to stop work. He was hospitalized February 1 and died May 3. From an autopsy the cause of death was diagnosed as "primary carcinoma of right testicle with carcinomatosis." His widow and children instituted proceedings under the workmen's compensation act of Utah and the industrial commission, which heard the proceeding, awarded compensation on a finding that the deceased had suffered an accidental injury, that the accident arose out of or in the course of his employment and that the accidental injury caused his death or aggravated and accelerated a preexisting condition which resulted in death. The employer appealed to the Supreme Court of Utah.

On appeal it was contended, apparently, that there was no evidence to justify the finding of the industrial commission that the accidental injury suffered by the deceased had caused his death or had aggravated or accelerated a preexisting condition which resulted in his death. As the commission indicated, said the Supreme Court of Utah, Jensen was probably suffering from carcinoma at the time of the industrial accident. Dr. Ogilvie testified before the commission that the cause of death was "primary carcinoma of the right testicle with carcinomatosis," but he refused to speculate on the question as to whether or not the injury accelerated the preexisting cancerous condition, stating that "sometimes trauma greatly accelerates the growth of cancer but sometimes it does not." The medical profession, continued the court, has been unable definitely to determine the

cause and cure of cancer and is hesitant to make any positive statement concerning it. We have here a situation in which the deceased received an injury to his right testicle. Swelling and pain immediately followed and became progressively worse, ending in death. The circumstantial evidence indicates that the injury aggravated and accelerated the cancerous condition contributing to the death of the worker. This is the more probable and rational explanation of the factors leading up to the death of the worker.

In this case, continued the court, there is no medical evidence on the question of whether or not the effect of the blow accelerated the preexisting condition, the medical witnesses refusing to speculate, but the commission drew the inference that there was a definite connection between the blow and the acceleration of the condition, because apparently the acceleration did begin with that event. To warrant recovery in such cases we do not think it necessary for the claimant to procure a physician who will make a positive statement, for it is obvious that no positive statement can be expected. Even physicians have no television of the pathologic history of the inside of a man. When the event of accident is definite and injures a particular member or part of the body and afterward disability or death occurs and the progression toward disability or death can definitely be ascertained as beginning with the former event because the history of the progression directly involves a worsening of the member or part to which the injury occurred or the evidence involves a connection between the trauma and other affected parts in the history of the progressive worsening, there will be sustaining evidence for an award. If there is a doubt introduced by a conflict of testimony before the industrial commission as to whether the accidental event was the cause of the disability, the decision of the commission as a resolution of that doubt will be sustained unless it appears to be so apparently against common sense as to be arbitrary. In this case, we cannot say that the commission was not justified in inferring that the trauma accelerated the cancerous condition contributing to the death of the worker, although an opposite finding could have been made. When two conflicting inferences might reasonably be drawn, this court will not reverse a decision which adopts the more probable of the two.

For the reasons stated, the award of compensation was affirmed.—*Utah Fuel Co v Industrial Commission, 126 P (2d) 1070 (Utah, 1942)*

Workmen's Compensation Acts Death from Cerebral Embolism Following Rupture of Left Saphenous Internal Vein—The workman, a school janitor, while pushing in the course of his employment a broom mop, weighing about 25 pounds, up a ramp, ruptured his left saphenous internal vein half way between the knee and the hip joint. From this thrombophlebitis in both legs and a series of pulmonary embolisms developed. One month and four days after the industrial accident he suffered a cerebral embolism or lesion causing a flaccid paralysis of the right side, from which he died six days later. Proceedings to recover compensation under the Utah workmen's compensation act were instituted by his widow but his employer denied that the cerebral emboli causing death resulted from the industrial accident. The industrial commission entered an order denying compensation on the ground that the death did not result from the industrial accident and the claimant, the widow, brought certiorari to the Supreme Court of Utah.

But one question is presented for our determination, said the Supreme Court. Was the commission arbitrary in not finding from the record that the cerebral embolism from which the worker died was the result of the industrial injury he suffered? Where the evidence before the industrial commission will sustain different conclusions, this court will not weigh the evidence and draw its own conclusion therefrom. The conclusion of the industrial commission will be upheld by this court if reasonable minds, in view of and from the evidence in the record could so conclude. But to sustain the conclusion of the commission the evidence must be substantial evidence, competent evidence, evidence on which a reasonable mind, a judicious mind, may be

content to rest its judgment. Is the conclusion of the commission that the cerebral embolism causing death was not a result of the rupture and thrombosis of the saphenous vein sustained by any substantial competent evidence? If there is substantial competent evidence to sustain it, then it cannot be said to be arbitrary or capricious. If on the other hand, there is no substantial competent evidence to sustain it, and there is material substantial competent, uncontradicted evidence impelling a contrary conclusion, then the holding of the commission would be unreasonable, arbitrary and capricious and could not stand.

All the evidence, continued the court, pertaining in any way or in any degree to the cause of death consists of the case record kept by the attending physician of the workman, in the death certificate issued by that physician, in the testimony of Dr Aird who during the period between the injury and death twice examined the workman in consultation with the attending physician, in the testimony of Dr Cullimore, who was called as an expert by the insurance carrier of the employer, and in a written expert opinion by Dr Viko based on an examination at the request of the industrial commission of the record after the conclusion of the hearing. The case record kept by the attending physician shows the industrial accident on January 13, the development of thrombophlebitis in the left leg and a series of pulmonary embolisms beginning February 4 all undisputedly caused by the thrombophlebitis in the leg. On February 14 a pulmonary embolism (this, the court remarking would result in increasing the pressure of the blood in the right auricle of the heart) was accompanied by a jerking of the left leg similar to that which often occurs on and is suggestive of a lesion of the middle left cerebral artery. On February 16 there was another pulmonary embolism (which would further increase the pressure of the blood in the right auricle of the heart). And there was also an embolism or plugging of an artery in the right leg and, on February 17, a cerebral embolus or lesion, evidenced by a jerking of the right leg and followed by paralysis of the right side from which death resulted on February 23. The record kept by the attending physician said the court concludes with a notation of death from 1 Cerebral embolus causing paralysis right side. 2 Following thrombosis left internal saphenous vein. The death certificate, executed by the attending physician reads "Immediate cause of death cerebral embolus causing paralysis right side. Due to Following thrombosis left internal saphenous vein. Due to rupture January 13."

The attending physician said the court, died before the hearing conducted by the industrial commission and so could not amplify his rather complete written records. Dr Aird testified at the hearing that during the illness of the workman he had twice visited him in consultation with the attending physician and found the patient suffering from thrombophlebitis as a result of the accident, also from pulmonary embolisms as a result of the leg conditions. In response to a question as to whether or not, in his opinion, death was connected with the industrial accident Dr Aird answered "Yes, I would be strongly of the opinion that it was. Undoubtedly to my mind he got an embolus from the lung condition to the brain." This physician attributed the lung disorder to an embolus and stated that it was possible to have a cerebral embolism from an embolism originating in the venous system in another part of the body. Dr Cullimore, called as an expert by the insurance carrier, in answer to a hypothetical question embracing most of the facts developed in the case, stated that, while it was questionable whether the accident was the direct cause of death, the accident probably was an indirect cause of death, the direct cause being the cerebral embolus. The indirect cause of death, according to this physician, could be an aftermath of the thrombosed vein, the physician stating

This man may have had a thrombus set up in a vein in the brain or he may have had it in the liver or any place because of the fact that he had it existing down here [in the leg]. This man had it extensive and it is more likely it was a migratory thing.

This witness thought that it was possible that there was a connection between the accident and the final cerebral condition.

The industrial commission, said the Supreme Court, on its own motion at the close of the hearing submitted the record to

Dr Viko for his opinion on a medical interpretation of the record. Viko expressed the opinion that the record was clear that the cerebral lesion which caused death was due to the emboli from the vein in the leg and he pointed out how in his opinion every step, even prior pulmonary embolisms, with consequent increase in auricular blood pressure, conditions conducive to and perhaps necessary for venous emboli passing into the general arterial systems, existed in this case, even timed right for such things to happen. Dr Viko stated in his opinion

The first of these considerations means that at the same time as the pulmonary embolism of February 14 there was a lesion though temporary of the left middle cerebral artery and the second consideration means that at the same time as the pulmonary embolism of February 16 there was a plugging of an artery in the right leg. The coincidence in the time of these widely separated occlusions of arteries in lung, leg and brain is too clear to justify one assuming that in the case of the lung artery the plugging was due to an embolism in the leg, and that the plugging of the other two arteries was independent thereof as if due to thrombosis or hemorrhage in each of those other arteries. It therefore seems only reasonable to assume that the plugging in each of the three arteries had a common origin and since it is noted above the origin of the pulmonary emboli lays almost certainly in a vein in the leg, that the plugging of the cerebral artery and the artery of the leg, was also due to the emboli from the vein in the leg.

The record of the attending physician, said the court, indicates that he considered the cerebral condition the result of the injury to the leg. Dr Aird's opinion was positive to the same effect. Dr Cullimore recognized the connection as probable and Dr Viko pointed out that any other conclusion would not be medically sound. As to the cerebral lesion being the result of an embolus from the leg, there was no difference of opinion among the physicians. As to the process by which the emboli passed from the leg to the brain, the physicians each described a different possible process. But the process or route traveled by the emboli is merely incidental. It enters into the picture only to see whether or not it is possible for thrombophlebitis in the leg to produce an arterial embolism in the brain. All the evidence is in accord that it can do so. And all the evidence is in accord that in this case it did do so. There was therefore no conflict in the evidence on any material issue. Since the industrial commission was not required to find and did not make a finding with respect to how the emboli from the leg reached the brain, but merely found it did not do so that finding is directly contrary to the undisputed evidence of all the physicians, not only that it could do so but that in this case it did do so. The Supreme Court therefore concluded that on the record submitted to it the evidence, uncontradicted and unquestioned, consistent with itself with all general knowledge and with medical knowledge, opinions and authorities, compels a finding that the cerebral embolism or lesion from which the workman died resulted from the leg condition, admittedly the result of the accident. The order of the industrial commission denying compensation was accordingly vacated and set aside.—*Peterson v Industrial Commission*, 129 P (2d) 263 (Utah 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Electrocardiographic and Clinical Study of Lanatoside C—Tandowsky compared the effect on the myocardium of lanatoside C given intravenously with that of digitalis purpurea orally. The criteria of a digitalis effect were the time necessary to obtain maximal depression of the RST segment in lead 2 of the electrocardiogram, the rapidity with which the signs and symptoms of congestive failure disappeared and the time required for the abolition of the segment changes. Twenty patients received 16 grams (1 Gm) of digitalis purpurea orally and 20 received a single dose of 1.6 mg of lanatoside C intravenously. Particular attention was given to the incidence of toxic effects. As control, each drug was given to 2 normal adults. Of the 20 patients given lanatoside C 2 died during the study, 1 from lobar pneumonia and 1 from myocardial infarction. The average time required for the maximal change in the RST segment was three hours and six and a half minutes. This average can be reduced to two hours and forty minutes if the psychotic patient in the series is excluded. Only 1 of the group suffered from nausea. Within three hours the average heart rate was reduced from 121 beats per minute to approximately 83. The 18 surviving patients presented definite clinical evidence of improvement within six hours. Delay in auriculo-ventricular conduction appeared to be the exception rather than the rule. One patient had a slight nausea for forty-eight hours after the administration of lanatoside C. In the 20 given digitalis purpurea the average time required for a maximal change in the RST segment was fourteen hours and twenty-four minutes. Eight of this group suffered from severe nausea and vomiting which were traceable to the drug. There was an average reduction in the heart rate of approximately 30 beats within twenty-four hours after the administration of the whole leaf. Not unlike the group given lanatoside C a gradual clinical improvement was apparent in twenty-four hours. The auricu-

lar fibrillation of 6 patients continued throughout the observation. Urinary excretion was increased in both groups. As all the patients continued to take digitalis after the study was discontinued, no return of the segments to normal was observed. The digitalis effect of lanatoside C on the RST segment of the 2 control subjects disappeared within sixteen hours, whereas this effect persisted for forty-eight hours or more in the control subjects given digitalis purpurea. It is clear that to retain the digitalis effect for a prolonged period lanatoside C must be given frequently, and it is therefore preferable to use a digitalis preparation containing all the glycosides when continued maintenance therapy is necessary. For those patients who do not require rapid digitalization or are not suffering from gastrointestinal disturbances, the preparations of digitalis now in common use are satisfactory.

Ligation of Descending Branch of Coronary Artery—Bradbury's examination of a woman thirty years after a stab wound in the left breast which severed the descending branch of the left coronary artery revealed no subjective symptoms of heart disease. Her blood pressure (at 75) was 170 systolic and 85 diastolic, the pulse rate was 80, the pulse was regular in rhythm but not in force, and the arteries were not particularly sclerotic. A roentgenogram of the thorax showed that the heart was not enlarged, there was good pulsation and no limitation of motion. The arch of the aorta showed definite calcification. The left half of the diaphragm was slightly elevated, but it moved freely and equally on respiration. Very slight enlargement both of the left ventricle and of the right outflow tract was revealed in an orthodiagram. An electrocardiogram showed an occasional premature beat, a rate of 88, a PR interval of 0.14 second, no axis deviation, inversion of T₂ and low voltage of QRS in lead 3. The chest lead was normal. Such a curve in a person of 75 is not diagnostic of heart disease.

The Obstructed Peptic Ulcer—Wilkinson reports the results of treatment in 100 cases of pyloric obstruction due to peptic ulcer prior to 1936. General principles of therapy consisted in bed rest, a bland diet with frequent feedings, moderate use of alkalis and aspiration of stomach contents once or twice a day until the obstruction was relieved or operation was performed. Many patients responded favorably to this regimen while they were hospitalized and were discharged symptom free. Some of these remained symptom free for years (a few for more than eight years) before obstructive symptoms developed again. Many more showed signs of obstruction as soon as they reentered active life and were forced to return for operation. Medical management was most useful for those in whom

obstruction was present less than three months, whereas in those with obstruction for longer periods recurrences were almost certain in spite of apparent complete relief. The ratio of males to females among the 100 patients was 3:1, whereas with ulcer in general the ratio is nearer 10:1. The probability of recurrence in women is 10 to 1 as compared to 3 to 1 in men. The principle of the treatment followed was never to have the stomach distended and gradually to decompress it.

Metabolic Disturbances in Workers Exposed to Dimethyltoluene—McGee and his collaborators present observations on 154 workers who came in close contact with dimethyltoluene for the first time during the past year. The workers were engaged in the manufacture of military powders. Their chief exposure to dimethyltoluene occurred in two places, designated as the 'D N T Screening House' and the 'Coating House'. One hundred and twelve men reported complaints on one or more examinations. During a period of twelve months only 42 never felt unwell. In 4 of the 42 anemia developed without other signs of illness. There was objective evidence of sickness during one or more examinations in 84 of the total group while 32 presented complaints without having any objective evidence of intoxication or illness. No workman was so seriously affected as to require hospitalization. The most frequent symptom was an unpleasant taste in the mouth. This was followed closely in frequency by sensations of muscular weakness, headache (mild to severe, intermittent or continuous), loss of appetite and sensations of giddiness, dizziness or drunkenness. Nausea and vomiting, difficulty in sleeping and pain, numbness and tingling, sensations in the extremities also were reported. On clinical examination the intoxicated workers were pale, cyanotic and anemic. Both pallor and cyanosis may be present in persons particularly sensitive to dimethyltoluene without a significant change in the blood counts. This was especially true of workmen in whom signs and symptoms developed during the first second or third day of exposure. The low incidence of leukocytosis and leukopenia suggests that alterations in the leukocyte count early in intoxication are of doubtful significance as far as dimethyltoluene is concerned. Twenty-three of the thirty-six anemias were of hyperchromic macrocytic type and thirteen were either normocytic-normochromic or slightly hypochromic. Symptoms of beginning intoxication disappeared within two or three days after workmen were no longer exposed. Cyanosis and pallor disappeared within a day or two. Some workmen recovered while they continued to be exposed. When anemia had developed (below 13.6 Gm. of hemoglobin per hundred cubic centimeters of blood and 4,000,000 erythrocytes) the count and hemoglobin value returned to normal slowly, in two months with presumably adequate doses of ferrous sulfate and in one month when crude liver extract and the iron medication was given. Careful and frequent reexamination of workmen exposed to dimethyltoluene appears to be essential in the proper supervision of certain operations.

Drip Method for Gastric Acidity—Cornell and his associates compared the clinical value of certain colloidal aluminum preparations with milk to which a soluble alkali had been added, used in the drip treatment of peptic ulcer, in day and night secretion of ambulatory and hospitalized patients. Three preparations investigated were effective as intragastric neutralizing agents even during prolonged night treatment. The average pH maintained by the aluminum phosphate and the milk-sodium bicarbonate preparations was around 4 and that of the aluminum hydroxide preparation was around 3.5, which is the boundary value for no free acid. In the control tests free acid was absent in only about 1 per cent of samples, with the milk and the aluminum hydroxide gel mixtures this occurred in about 53 per cent and with the aluminum phosphate preparation in about 60 per cent. These data indicate that none of the drip therapy procedures succeeded in maintaining the stomach free of acid throughout the entire period of treatment. On the other hand, the proportion of high pH values indicates considerable efficiency in acidity reduction. The high and the mean pH may be materially increased by increasing the concentration of antacid in the drip fluid and by elevating the rate of flow above that employed throughout the treatment. The apparent antacid

superiority of the phosphate gel over the aluminum hydroxide and milk-sodium bicarbonate preparations may have been due to the use of the aluminum phosphate mixture without dilution.

Encephalitis Following Vaccination with 17D Yellow Fever Virus—Fox and his colleagues summarize the history of vaccination against yellow fever in Brazil, where more than 2,000,000 persons have been vaccinated with the 17D strain of yellow fever virus. Up to July 1941 no encephalitic reactions occurred. However, in July 1941 persons manifesting definite symptoms of encephalitis were discovered among those who had recently been vaccinated against yellow fever. These reactions followed routine vaccination against the disease with a series of vaccine lots derived from a single substrain of the 17D virus. Of 55,073 persons vaccinated in the area most extensively investigated, 273 (0.5 per cent) experienced abnormally severe reactions. 199 of them presented some evidence of involvement of the central nervous system. Only one fatality is known to have occurred. The reactions were more frequent among young persons. Although only a half of the population of the area had been vaccinated, only 10 clinically similar cases occurred among the unvaccinated. Demonstration of a relatively uniform post-vaccination incubation period is believed to establish firmly the causal relation of vaccination to the cases. Evidence could not be obtained that an extrinsic etiologic agent was responsible. These conclusions were supported by a well controlled field trial in which the effects of the indicted substrain with four other 17D substrains and one vaccine containing no virus were compared. Three of the other four substrains also manifested, though in much lesser degree, a tendency to cause encephalitic reactions. The field experiment further emphasized the usual early occurrence (sixth to eighth day) of the mild reactions and the later occurrence (tenth or later postvaccination day) of the more severe reactions. Evidence indicates that a "variation" had occurred in the 17D substrain used, and that this and not some adventitious agent was responsible for the reactions.

Leptospirosis in New York City—During the last four years Tiffany and Martorano have encountered or aided in the diagnosis of leptospiral jaundice in 10 human beings in New York City. In only about a half of the patients with Weil's disease does jaundice develop and, unless physicians always keep the disease in mind, many cases will pass unsuspected or be incorrectly diagnosed. The incidence of leptospiral infection in human beings in New York City was investigated by testing the blood serum of certain groups among the population for agglutinins for Leptospira to discover how frequently the serums of persons suffering from some illness other than leptospirosis give falsely positive reactions. Blood samples from 1,351 individuals were examined. The specimens of 10 showed a positive reaction to an agglutination test of a titer of 1:320 or more, 8 gave a history of a past illness consistent with

Weil's disease. Forty three gave positive reactions to a titer of 1:100 or less, only 3 had a history of a suggestive past illness. The strongest positive reactions were among those whose work exposed them to rat infested surroundings. In only 2 of the positive reactors had the diagnosis of Weil's disease been made during the illness. The presence of antibodies for members of the typhoid group, Brucella or the Wassermann antigen did not cause false positive reactions with the leptospira antigen. No reactions against Leptospira icterohemorrhagica were found among the serums of 59 persons whose work brought them into frequent contact with dogs. The attending physician should be alert to the diagnosis of leptospirosis when he encounters in acute febrile illness, even without jaundice, in one whose work is likely to involve exposure to rat contaminated surfaces and especially if the illness resembles influenza pneumonia or typhoid or if renal insufficiency or a hemorrhagic tendency is present.

Variations in Multiple Sternal Marrow Samples.—Reich and Kolb made qualitative and rough quantitative determinations of multiple sternal marrow samples. The highest mean and standard deviation for the leukocyte count was observed among diseases of the nervous system, and the highest and most variable average number of polymorphonuclears was observed among diseases of the blood forming organs. As the number of polymorphonuclears is a factor in the total count, and as two counts from a single sample tended to be more alike than four counts from two samples taken simultaneously, sufficient variation was observed in the four counts to lessen considerably the dependence which could be placed on a single quantitative estimate of the number of cells in a single sample. These observations would indicate that the validity of quantitative marrow determinations is questionable. Consequently, it seems inadvisable to continue the use of detailed quantitative data or indexes in conjunction with sternal marrow finding. This does not belittle or detract from the importance of qualitative marrow studies in establishing hematologic diagnoses.

Amphetamine Sulfate in Migraine.—Results with amphetamine sulfate in migraine, as presented by Gottlieb, suggest

that the drug may be useful in the treatment of this disease. Regardless of the basic pathogenesis of migraine, evidence implicates a local disturbance of the arterial system, angiospasm or dilatation, as the immediate causal agent for a paroxysm. Amphetamine sulfate was selected because it is a sympathomimetic compound with a prolonged action and because vasoconstriction with its concomitant pressor effects was desired. As the drug can also produce intense restlessness, insomnia and cardiac irregularity, depending on idiosyncrasy, it is contraindicated for patients with cardiovascular disease, particularly those with hypertension. It must be administered with due caution. The drug was given to 25 patients suffering from typical migraine but free from other disease. If the patients reported to the hospital during an attack, the drug was administered intravenously in 3 to 20 mg doses. The rate of injection was 1 mg per minute for the first injection. If no untoward symptoms developed, the speed of injection was increased according to individual sensitivity as revealed by the rise in blood pressure taken at minute intervals. An increase of 20 to 40 mm of mercury in the systolic blood pressure was used as the criterion. Following testing of their response to intravenous medication the patients were advised to take the drug orally in 10 to 40 mg doses at the beginning of an attack. The 7 of the 25 patients who were examined between attacks were placed directly on oral medication. Eighteen of the patients received amphetamine sulfate intravenously from one to seven times and 12 of them consistently obtained complete relief from attacks in from seven to forty-five minutes. Three of the 12 on some occasions had a recurrence of symptoms after four hours. These subsequent symptoms were relieved by further intravenous medication. Of the 6 who failed to obtain relief 2 did so regularly from ergotamine tartrate, 1 from oxygen therapy and the other 3 failed to respond to any therapy. Of the 7 on oral therapy 5 were improved within sixty minutes and 2 were not. In contrast to these 25 patients with mild and infrequent paroxysms were 3 who had frequent severe attacks. They responded well to amphetamine sulfate when it was given intravenously. As the frequency of their paroxysms was a serious problem the drug was tried orally in divided doses as a prophylactic agent. A maintenance dose which relieved them of their paroxysms, yet was not sufficient to cause toxic manifestations, was found for each of the 3.

Osteopoikilosis—Ritterhoff and Oscherwitz cite a case of osteopoikilosis associated with gastric adenocarcinoma and bronchogenic carcinoma. They were not able to find reports of a similar case. The abnormal densities in the bones of the shoulder girdle in the first roentgenogram of the chest could have been confused with metastasis from a pulmonary carcinoma. This was obviated by subsequent roentgen examination of the entire skeleton, which revealed the typical symmetrical widespread involvement of osteopoikilosis. The important clinical problem in the case was the differential diagnosis between tuberculosis and carcinoma of the lung. The initial occurrence of a chronic lung disease in an elderly white man with no previous history of tuberculosis should be more suggestive of a neoplastic rather than a tuberculous process, particularly when the unfavorable course is associated with stationary roentgen observations of the lungs and the failure to demonstrate tubercle bacilli.

Contact Roentgen Therapy—The results in the first hundred lesions treated with contact or short distance roentgen therapy at the Brooklyn Cancer Institute are described by Howes and Camel. Of 55 various basal carcinomas, 41 of 42

considered curable when first seen were controlled, in 1 the result was poor, although the condition was controlled, in 7 the therapy was palliative and the lesions of 3 were controlled, of 2 well palliated and in 2 the result was poor, 3 of 4 rodent basal cell ulcers appear controlled and 1 is progressing, the lesion of 1 patient in whom there was no biopsy is controlled, as is the clinical basal cell necrotic tissue of 1. The squamous cell carcinoma of the skin of 7 patients, judged curable and treated as basal cell lesions, was controlled, 1 after a second treatment. Three squamous cell carcinomas of the lower lip were treated successfully. The lesions of 12 patients with advanced or intractable squamous cell carcinoma treated for palliative or psychotherapeutic reasons were generally diminished in size, the exuberant overgrowths were flattened down and troublesome discharge and odor were lessened. Although it is improbable that this method of therapy will supplant older methods in the treatment of adenocarcinoma, 1 primary and 8 metastatic adenocarcinomas were palliatively treated and the local area reacted favorably with a decrease in size and diminution in troublesome discharge. Contact roentgen therapy was used on 4 patients as a keratotic prophylactic. A dosage of 3,000 to 6,000 roentgens at one sitting has been found sufficient to eradicate these lesions. The remaining 10 patients had leprosy disease, verrucae and corns, furunculosis and acne or angiomata, the condition of 7 was cured or controlled and on 3 (the 1 with furunculosis and acne keloid and the 2 with hemangiomas) the results were inconclusive. However, recent experience in hemangioma shows that results are most encouraging with an exposure of 600 to 1,000 roentgens without filter. Hemangiomas of the cavernous type should be treated with 1 mm of aluminum filter. Patients with most of the other lesions were exposed to roentgen rays generated at 45 kilovolts, 2 milliamperes, 18 cm target skin distance and no filter. Depending on the lesion and the site to be treated, the dosage varied from 3,000 to 13,000 roentgens.

Ruptured Intervertebral Disk—Eck reviews 250 consecutive cases in which surgical treatment was given for pain in the back due to rupture of the intervertebral disk. Its predisposing cause is weakness of the annulus fibrosus, and trauma is its precipitating factor. Another etiologic factor to be con-

sidered is calcification of the entire disk. The predisposing factor, anatomic weakness, may exist in many instances without rupture ever taking place. Trauma may be violent or severe or one of repeated minimal traumatic shocks. The rupture occurs with the spine in flexion on the occasion of trauma. Rupture occurred in the lumbar region in 213 of the 250 cases, in the cervical region in 5 and in the thoracic region in 2. Rupture usually occurs in the region of greatest lordosis. The symptoms vary with the anatomic region involved. Laboratory study is of diagnostic assistance. Spinal puncture will usually accelerate pain, especially when the lumbar area is involved. The Queckenstedt test may indicate a partial block in the thoracic and cervical regions. A positive increase of the spinal fluid protein aids in substantiating and verifying the diagnosis. Roentgen study differentiates rupture of the intervertebral disk from conditions which it simulates—tumors of the spinal cord and surrounding osseous tissues, fractures of the vertebrae without rupture of the disk, congenital anomalies and various arthritic conditions. In the presence of a reasonably positive diagnosis and persistence of symptoms despite conservative measures (traction, immobilization and physical therapy) treatment is extradural removal or partial hemilaminectomy. Laminectomy is rarely necessary. Spinal fusion is not required when little bone has been sacrificed. If postoperative pain is relieved by a brace, the brace is indicated as a stabilizing factor. Why only some patients complain of pain, which is relieved by fusion, is not yet adequately answered.

Diagnosis and Treatment of Pancreatic Disease.—According to Cimha chronic pancreatitis should be suspected when the roentgenologist reports that the function of the gall bladder is not disturbed and that gallstones are absent yet the patient continues to complain of symptoms referable to the gallbladder. Hyperinsulinism may be a clinical manifestation of chronic pancreatitis. When patients complain of vague gastrointestinal distress with definite dizziness, body trembling, or syncope, hyperinsulinism and hypoglycemia should be suspected and more accurate blood sugar studies made, particularly dextrose tolerance curves in six hours and hyperinsulinism interpreted as a manifestation of a disturbed function of the pancreatic tissue, a pancreatitis. In chronic alcoholism with its prominent symptoms of hunger and weakness, chronic pancreatitis should be suspected. Studies of the blood sugar and determination of the pancreatic ferment in gastrointestinal examinations may often suggest the pathologic conditions present. The author emphasizes five points in the therapy of chronic pancreatitis: a high carbohydrate intake to stimulate the production of amyllopsin, elimination of direct pancreatic depressants, small doses of hydrochloric acid for patients with associated hypochlorhydria, vitamin A and iron in readily assimilable form and pancreas substance. An apparently nonfunctioning gallbladder, one that fails to respond in a reasonable length of time to accepted methods of medical therapy, should be removed. This eliminates the hazard of a possible acute pancreatitis later. Perhaps the most recent valuable therapeutic addition for the acute phase of pancreatic disease has been ephedrine.

Chorioepithelioma in Male.—Bonn and Evans report the sixth case of extragenital chorioepithelioma in the male. The case apparently fulfils the criteria necessary for extragenital origin. First, serial block sections of the testes were negative. Sixty-two sections were made without finding a primary testicular tumor. There was an area in one testis which showed a scar, but in this testis there was no tissue suggestive of malignant change. It is possible that the scar in the one testis may have been related to traumatic inflammation or even its rupture from the kick of a horse received at the age of 14 (34 at death). Second, at necropsy chorioepitheliomatous tissue was found in the lungs, mediastinal and tracheobronchial nodes, spleen and in a solitary retroperitoneal lymph node. Third, abnormal amounts of the sex hormones were found in the urine and in the tissue of the chorioepitheliomatous masses in the lungs. Fourth, there was a true gynecomastia of both breasts.

Primary Tuberculosis.—Of the four possible types of primary tuberculosis (the primary complex that soon heals, the primary complex that proves rapidly fatal, the one that progresses and the epituberculosis that masquerades as extensive pulmonary tuberculosis or tuberculous pneumonia) Jones and her co-workers discuss the last and state that the average case in this group presents a clinically typical complex. It occurs seldom in adults, is often characterized by physical signs of lobar consolidation, the roentgen shadow is dense, homogeneous and lobar in extent, the sputum is scanty or absent and nearly always negative to ordinary microscopic study. The child with this disease appears to be in surprisingly good health and exhibits a strong reaction to tuberculin and after months without change, resolution sets in and clinical and roentgen recovery is the rule. It is the authors' belief that bronchial obstruction with atelectasis forms the basis for many of the cases and that the primary focus in the lung is followed soon by disease and enlargement of the lymph nodes at the root. To these two factors which coexist must be added a third factor—that of interference with bronchial drainage and aeration. This may be brought about by simple mechanical pressure from the enlarged lymph nodes but probably more often by direct extension of the tuberculous process from the nodes into the bronchial walls. The disease may remain in the submucosa or it may break through an ulcer or tuberculoma. The tuberculous disease, with its attendant collateral inflammation and edema, leads to paralysis of the ciliary and peristaltic motion in the area and thus there is a break in the continuity of the drainage mechanism with consequent functional, if not complete structural, blockage. These views grew out of the authors seeing 85 such tuberculous children among 716 admitted to the Children's Division of the Maybury Sanatorium. The admissions included all types of tuberculosis occurring in children. Bronchoscopic examination of 42 of the 85 children revealed that in 31, or 74 per cent, bronchial distortion or disease was present chiefly as narrowing of the lumen from pressure by enlarged lymph nodes at the root, tuberculoma and ulceration. Edema, redness and secretions were present in many. In 11 no bronchial abnormality was observed. The term epituberculosis has for many years been used to designate a clinical syndrome which is characterized by lobar consolidation,

is benign in nature and occurs in tuberculin positive children. The pathologic basis for it has never been understood clearly. Therefore the term is no longer needed and should be replaced by lobar or lobular atelectasis.

Hemorrhagic Reaction to Purified Protein Derivative—Urbach and Goldburgh report a case of tuberculous lymphadenitis in which 0.000 002 mg of purified protein derivative of tuberculin injected intracutaneously was followed by a severe hemorrhagic-necrotic local reaction, septic fever and thrombocytopenia. This was an expression of hypersensitiveness which corresponds clinically and microscopically to the Schwartzman phenomenon. As the manifestations were elicited only by tuberculin—and not by streptococcus vaccine—the possibility of a specific anaphylactic reaction, the Arthus phenomenon, must be considered.

Treatment of Addison's Disease—Engel and his associates have now treated 8 patients with Addison's disease by implanting pellets of desoxycorticosterone acetate. A few of them have now been so treated for more than two and a half years. Three of the 8 patients are women and 5 are men, their ages vary from 21 to 57 years. A tuberculous etiology is definite in 3 and probable in 3 others. If proper precautions are taken, excellent results may be achieved. Not only are the abnormalities in electrolyte balance and blood pressure regulation completely alleviated, but a striking improvement in the strength and well being of the patient ensues. Failure to obtain improvement is usually attributable to insufficient dosage or overdosage of the drug or to the fact that the patient's symptoms are due predominantly to disturbances in carbohydrate metabolism. The authors believe that it is best to implant fewer pellets than the required number and to supplement the treatment with some additional salt by mouth daily. In this way the dangers of unfortunate complications are lessened. By the sublingual route larger doses of the drug are needed for effectiveness than by the intramuscular route. As the drug probably is rapidly absorbed into the blood stream when it is administered sublingually it should be given in small, frequent doses to produce an even effect. The ideal method is to provide a slow, steady release of hormone all day, a result which is best achieved by pellet implantation. To obtain satisfactory results by pellet implantation a prolonged period of observation on treatment by the intramuscular route is necessary before implantation is carried out. During the first few months of treatment with the synthetic hormone a gradual decrease in requirement occurs. If implantation is done before the minimal requirement has been determined, what was an adequate dose at the time of implantation will prove to be a toxic one several months later. When the smallest maintenance dose has been determined, the number of pellets to implant is calculated on the basis that each pellet yields daily approximately 0.3 mg of the hormone. The requirement by pellet is about 60 per cent of that required by the intramuscular route. Pellets of approximately 125 mg in size should last about eleven months. Toxic reactions can usually be avoided by extreme caution in the dose used.

Use of Cold in Medicine—Smith reviews the many uses which cold has found in medical therapy. He states that in spite of centuries of almost subconscious recognition of the usefulness of cold in the treatment of pain and fever, perhaps because of its very simplicity, its more extended use has only just begun. Its use has pointed the way toward a new era for the diabetic patient and for military and civilian traumatic injuries of the extremities. The work of Talbot with generalized hypothermia in schizophrenia likewise opens the entire field of the central nervous disorders to similar investigation. In malignant disease, evidence has conclusively shown the value of hypothermia in both its localized and its generalized application as an adjunct to other methods of treatment, and especially in the terminal stage of the disease. Its value in the control of pain is often truly phenomenal and for this reason alone the method should be employed widely in a variety of painful diseases. Its use in the treatment of narcotism and local control of infection appears proved. Perhaps as knowledge grows it may be possible to reach safely the "critical" levels of tumor cell growth that tissue cultures suggest may be destructive to cancerous cells and thus add a truly effective weapon to the eradication of malignant disease. Like any other major therapeutic procedure it is not without certain dangers, which must be recognized and methods designed to counteract them, therefore during its experimental stage it is best that its application be limited to institutions that are staffed and equipped to handle them properly.

Detection of Subclinical Scurvy—Rinehart and Greenberg have tried to determine the degree of tissue depletion existing in adults with low plasma ascorbic acid values and whether or not this depletion has deleteriously affected the health of the persons involved. Thus, of 34 adults with fasting plasma ascorbic acid values from 0.0 to 0.1 mg per hundred cubic centimeters, 15 showed flat curves representing an average deficit of 2.16 Gm. The remaining 6 exhibited high curves. With few exceptions, adults with initial blood plasma values above 0.3 mg were near saturation and excreted from 50 to 300 mg of the ingested test dose of ascorbic acid. As in most subclinical deficiency states the effect on the general health and well being of the patient following correction of the deficiency is perhaps the clearest evidence that deficiency existed. Twenty-three of 27 persons with an initial plasma vitamin C concentration below 0.1 mg showed improvement after their vitamin C deficiency was corrected. Approximately 80 per cent of the adults in the series in whom the initial fasting blood plasma ascorbic acid was below 0.1 mg were suffering from a subclinical form of vitamin C deficiency, though none presented a clinical picture that could be called scurvy. Vitamin C deficiency of the type described is frequently encountered, as of 239 "normals" consisting of students, nurses, house officers and laboratory workers 46 per cent showed fasting blood plasma levels below 0.1 mg and 16 per cent below 0.3 mg per hundred cubic centimeters. Determination of the fasting plasma ascorbic acid is the simplest and most direct exploratory objective method in detecting subclinical vitamin C deficiency or scurvy. Other less diagnostic but objective criteria are lowered capillary strength, mild reticulocyte responses following the administration of vitamin C, general symptoms of malaise, gingivitis, gingivostomatitis and unexplained bleeding. Unpublished observations indicate that vitamin C deficiency or subclinical scurvy of the type described is commonly encountered in medical practice.

Pneumococcal Meningitis—The cases of pneumococcal meningitis treated at the Cincinnati General Hospital from 1936 through 1941 form the basis for Rueggesser's discussion. There is no record at the hospital of the recovery of a patient from the disease prior to 1937. Successful treatment depends, in the main, on prompt and vigorous sulfonamide therapy, intravenous injection of specific concentrated serum and the drainage of accessible foci of pneumococcal pus. The case mortality rate of pneumococcal meningitis has been lowered all over the world. It is hazardous to be more specific, as reports of recoveries are much more likely to be published than are the failures. This saving of lives affects all age groups, and especially those between 1 and 20. The prognosis in infancy remains grave. The improved method of treatment has no predilection for a certain type of pneumococcus, and there is no evidence that any

certain type is especially resistant to this therapy. In fact the percentage increase of cures of type III pneumococcal meningitis is striking in view of the mortality of type III pneumococcal pneumonia. Meningitis secondary to infections within the head or injuries to the head has been more invariable than that secondary to pneumonia. Neel, Applebaum and Jackson in an analysis of their own 30 cases concluded that bacteremia had no particular bearing on the outcome of the disease. The authors' analysis of 637 cases collected from the literature compels him to the opposite conclusion. Of the 296 patients that recovered, the cultures of only 31 were positive; those of 57 were negative and of the remainder either cultures were not done or they were not reported. Of the 341 patients who died 74 had bacteremia, the blood cultures of 33 were negative and cultures of the blood of the remainder were not taken.

Cerebral Lesions After Neoarsphenamine Therapy—

Courville and Marh discuss the significance of associated symmetrical foci of hemorrhagic necrosis in post-arsphenamine hemorrhagic encephalitis. This lesion has heretofore not been studied. From a review of the reported cases of hemorrhagic encephalitis in which larger foci of hemorrhagic necrosis are mentioned and of the cases that they have encountered it is clear that in addition to widely scattered 'flea bite' hemorrhages which occur in the brain, areas of hemorrhagic necrosis may be found associated with smaller discrete hemorrhages or occurring as separate and distinct lesions. The clinical factors in the two types of cases appear similar, with the same tendency to occur in young women within a few days of an ordinary therapeutic dose of neoarsphenamine. The chief difference was the greater tendency for the occurrence of focal neurologic signs in the cases with the larger symmetrical foci of necrosis particularly in the form of motor phenomena. In the 12 cases of cerebral lesions following neoarsphenamine (or some allied arsenical) therapy that were available for study four general types of lesions were evident: (1) petechial hemorrhages scattered generally throughout the white matter of the brain; typical hemorrhagic encephalitis; (2) gross cerebral hemorrhage; (3) multiple and usually symmetrical foci of red softening involving both the gray and the white matter of the brain; and (4) a combination of any two (or possibly three) of these lesions. Among the 12 cases there were 4 or multiple petechial hemorrhage, 1 or gross cerebral hemorrhage, 6 or multiple symmetrical foci of red softening and 1 of both disseminated hemorrhage and symmetrical foci of red softening. If the few cases are typical then the lesion of multiple foci of red softening is the most common one after arsphenamine intoxication and the real nature of some of these lesions must have been misunderstood. The tendency of the lesion to occur in symmetrical areas of the brain suggests a vascular basis; perhaps the focal blood vessels supplying the areas are susceptible to the toxic agent to the same degree at the same time. If Ehrlich's original premise about lack of epinephrine is correct then it can be assumed that these vessels are most sensitive to the toxic process during episodes of vasodilatation. As is true of disseminated petechial hemorrhages, this lesion is not necessarily fatal. There was a case with a rather long survival period although serious clinical residuals are likely in the lesions are at all widespread or severe. Localizing or lateralizing clinical phenomena should suggest this particular lesion.

Archives of Internal Medicine, Chicago

Atypical Pneumonias—Indirect evidence of infection with psittacosis virus or the related viruses of a psittacosis-like disease (ornithosis) meningopneumonitis and venereal lymphogranuloma obtained by complement fixation tests in 4 of 8 cases of a condition regarded as "virus" pneumonia, is presented by Reimann and his associates. Serum in 1 of the cases gave strong protection against the virus of lymphocytic choriomeningitis. Therefore any one of these viruses may be the cause of a form of virus pneumonia which term is established to include a syndrome or a group of entities which may be clinically indistinguishable yet may be caused by a variety of known filtrable viruses. Clinically similar pulmonary infection caused by known agents other than filtrable viruses, and agents not yet determined may at present best be termed primary atypical pneumonia etiology unknown.

Diabetes Mellitus—The relation between the amount of insulin needed and the duration of the existing diabetes at various ages was determined by Colwell in 166 patients who were treated under uniform conditions. The ages of the patients ranged from 6 to 82 years. No acute complication was present in any patient at the time of study. Some chronic complications existed especially among the older patients. The age at onset varied between 2 and 77 years. From the data obtained the author infers that diabetes is inherent and begins at birth. Before it is recognized clinically its extensive progress is fully as great as it is after the disease is recognized. The rate of the progress is indicated by the age at which it is recognized; the earlier it appears the more rapidly it progresses. It is probably more nearly correct to say that the more rapidly it progresses through its unrecognized stage the earlier in life it appears. During the first few years after its recognition the diabetes tends to improve temporarily, probably as a result of treatment. This improvement does not affect its subsequent course. After ten years of known existence, progressive and permanent improvement may be evinced. In aged persons with diabetes, probably because of chronic complications, the foregoing premises are often violated.

Typhus Fever in California—Halveron points out that typhus fever or the endemic or flea borne type is prevalent in the southeastern part of the United States and occurs in California, 2780 cases were reported in 1941. Among the 229 cases reported from California since 1916 there have been five deaths. Typhus is spread widely over the world, and in Europe epidemic or louse borne typhus is increasing. The disease presents a grave potential danger because of military and industrial concentration of men and workers. Prevention by vaccination is in the trial stage. In 24 of the 37 patients observed at the Los Angeles County Hospital the onset was abrupt, 32 reported chills at the onset. In 15 this symptom was present

for the first four or five days of the illness. The temperature ranged from 101 to 105.6 F with an average of 103.5 F. Every patient except 1 complained of headache as a prominent symptom and 22 had generalized aching, usually of the large muscles. Backache was present in 15. The rash is usually seen on the fifth day of illness. Usually the leukocyte count is not elevated in endemic typhus. In this country the most common disease with which typhus can be confused after the rash appears is Rocky Mountain spotted fever. Both diseases are caused by rickettsia, the prodromal symptoms are similar and in both a rash occurs several days after the onset. Measles may be confusing if photophobia occurs as a prodromal symptom. The preeruptive stage is similar to early influenza. In the tropics malaria must be differentiated.

Nonhypoglycemic Insulin Reactions—Watson states that the incidence of allergic or nonhypoglycemic reactions (localized or generalized cutaneous manifestations) to insulin has been reported by different observers as 1 to 30 per cent. So called insulin allergy has developed in approximately 5 per cent of the author's insulin treated diabetic patients. Anaphylactoid reactions to insulin fortunately are rare. Apparently a state of hypersensitiveness to insulin in a diabetic patient usually does not modify the influence the hormone has on the blood sugar. A few instances of insulin hypersensitiveness have been reported to be related to a condition of insulin resistance. Apart from the occasional association of insulin allergy and the biochemical unresponsiveness to insulin therapy, no fatalities have occurred as a direct result of anaphylaxis. Nevertheless, any suggestion that a patient may be sensitive to insulin should not be disregarded, rather the indication is to proceed with caution, especially when insulin therapy is to be resumed after treatment is interrupted. Interruption of treatment may aid the diabetic patient to desensitize himself, or difficulties may be overcome by the discontinuance if the therapy is not essential for the treatment of the patient. Some benefit may be derived from reducing the dose or the number of injections, or by changing to a more concentrated insulin. However, a change to an insulin of a different biologic source is not helpful, except in rare instances, as the sensitizing agent rests in the molecular structure of the insulin itself. When the adequate treatment of a patient depends on insulin, a program of artificial desensitization must be considered. Desensitization is not always successful.

Silent Bronchopneumonia—Since roentgenography has become a routine in the Canadian forces, Andrus states that 96 cases of acute pulmonary exudation have been encountered in his military district. These cases would presumably have escaped detection if it had not been for the "accident" of roentgen examination resulting from war conditions. The cases may be termed silent, concealed or undiagnosed bronchopneumonia. That the pneumonia-like lesions were exudative and inflammatory in

character rather than sterile regional atelectasis, as might otherwise be suspected, was indicated by the fact that the erythrocyte sedimentation rate in all the cases examined was well elevated while the shadow existed. The cases have been called "silent" because conspicuous toxemia, blood spitting, chills and/or crepitant rales were absent. Silent bronchopneumonia has been regarded as probably the result of a low virulence of the causative organism. However, serial roentgenography during clinical manifest bronchopneumonia reveals another possibility. Roentgenograms at the stage of apparent clinical cure showed that the greater part of the pneumonic deposit was still present. In the subsequent ten to twenty days the exudate disappeared. Presuming that the febrile stage represents the development of immunity to the micro organisms concerned the disappearance of the exudate and the dissipation of atelectasis may, in fact usually does, substantially postdate the establishment of specific immunity. This alternate hypothesis provides an explanation for "silent" bronchopneumonia. So called silent bronchopneumonia is probably merely an instance in which the diagnosis was accidentally first made in the post toxic stage of bronchopneumonia but before resolution of exudate was completed. Therefore, in the absence of roentgenography, it is safest to regard and manage all manifestations of intercurrent respiratory disease as possible cases of bronchopneumonia. Most of the 96 recruits admitted an antecedent respiratory infection.

Is Pneumonia a Complication of Silicosis?—In an attempt to answer this question Pierpont consulted the health departments of the states of Michigan and Wisconsin as to the incidence and mortality rate of acute lobar pneumonia in the counties in which iron mining is the chief industry. The data from the mortality statistics received show that the mortality rate from acute lobar pneumonia is less in the counties where iron ore mining is the chief industry than it is in the states as a whole. On the Gogebic Range, in Gogebic County, Mich, and Iron County, Wis, the mortality rate is practically the same for underground workers as it is for other males of the same age who work on the surface. Men with silicosis get pneumonia just as do men of the same age without silicosis. Acute lobar pneumonia is an infectious and not an industrial disease.

Administration of Fluid to Surgical Patients—Wangensteen discusses the four essential problems which have a bearing on the fluid requirements of patients undergoing operation: (1) water requirement, (2) electrolyte needs, (3) blood loss factor and (4) the maintenance of the caloric and nitrogen balance. By proper attention to the administration of fluid to surgical patients, many operations may be extended to the poor risk patient without increasing the operative risk materially. Surgeons should interest themselves more in precise means of determining whether these needs of the patient have been satis-

fied. Weighing the patient preoperatively and postoperatively is the most precise method of determining the status of hydration. Similarly, the employment of weighed dry sponges during operation permits an accurate estimation of the blood loss by weighing the used sponges. If by fluids the preoperative weight has been exceeded and enough fluid has been given so that a satisfactory urinary output reasonably could be expected and oliguria continues, there is no need to give more fluid. The continued administration of fluid to such a patient will cause cardiac failure, pulmonary edema and death. Weight increases of 4 to 5 per cent over the patient's preoperative weight speak significantly for overhydration of the patient. As to the kind of fluid to be given, the author has followed the suggestions of Gamble employing solutions of salt and dextrose to replace decreases in extracellular fluid and electrolyte disturbances, with complete satisfaction. Large blood losses are preferably replaced by blood. When multiple transfusions become necessary, the suggestions of DeGowin, providing an alkaline urine by the intravenous administration of sodium bicarbonate solution (250 cc of a 5 per cent solution), should be followed. DeGowin contends that albumin casts are less likely to form, attending hemolytic reactions, if the urine is alkaline.

Trauma of Skin—Downing states that the recognition and elimination of an industrial dermatitis, such as may occur in the manufacture of clothing, explosives and food, may often prevent similar occurrences in soldiers who in turn come in contact with the articles. No new substances or processes should be introduced and the resulting article put on the market until their possible effects on the workers have been thoroughly investigated. In military life the possibilities for cutaneous diseases are similar to those of industrial and civilian life, varying from sensitivity to clothing and bakers' eczema from cinnamon or the persulfates to burns from explosives and gases and infections regarded in civil life as trivial and belonging to the unwashed. A knowledge of dermatology, always important in civilian life, is most essential in industrial and military organizations.

Cod Liver Oil Therapy of Wounds and Burns—Hardin used cod liver oil for the treatment of 346 various types of wounds and burns. Healing was more rapid than that following other methods. Cod liver oil is so effective in cleaning up infected wounds and stimulating healing that it replaces diluted solution of sodium hypochlorite. It is an effective method for treating the most severe major burns and is superior in certain respects to other methods of local therapy especially in third degree burns in which cod liver oil reduces infection, forms no adherent coagulum, destroys no epithelial elements and minimizes skin grafting. Commercial ointments were superior to home made preparations, in which odor, the only real disadvantage of the therapy, is disagreeable.

Secondary Coccidioidomycosis—Caldwell discusses the 7 cases of coccidioidal granuloma that he has had occasion to study. Three of them were reported in 1932, and the other 4 are reported for the first time. He states that certainly 5 of

the 7 patients contracted the disease in Texas. The histories of the other 2 are inadequate to conclude where the infection occurred. In 1 it is probable that the infection was acquired in California, while in the other 1 there are no data concerning place of residence or travel, and none can be secured. In none of the 7 is there any definite evidence that the primary infection occurred in the skin, although in 1 instance ulcers of the legs, which were thought to be varicose ulcers, might possibly have served as the port through which the chlamydospores of *Coccidioides immitis* entered. However, this seems unlikely. Most of the 7 patients had an initial acute coccidioidomycosis which involved the respiratory passages. If the ratio of acute cases of coccidioidal granuloma is around 300 to 1 or even 700 to 1, an appalling number of them are being overlooked in the various communities from which coccidioidal granuloma is reported.

Coccidioidal Granuloma in Texas—Smith emphasizes the dermatologic phases of coccidioidal granuloma and reports the 5 cases that he encountered in El Paso. Only 1 of the patients had been out of the state, in California. The cutaneous lesions usually assume one to two forms: chronic draining sinuses originating from subcutaneous abscesses, bone or other underlying involved tissues, and the hypertrophic or verrucous, blastomycosis like lesions with milium abscesses. The cauliflower like tumor masses that Lehmann and Pipkin observed are apparently exaggerated examples of the latter type of lesion. The diagnosis is made by finding the organism in the pus draining from the sinuses or from the milium abscesses. Intradermal cutaneous tests with a filtrate obtained from a broth culture of *Coccidioides immitis* are positive in twenty-four to forty-eight hours. This capacity to react is usually retained for years or throughout life. The multiplicity of remedies suggests that there is no dependable specific agent. The 3 or the 5 patients regarded as cured received colloidal iodine intravenously or intramuscularly, and instillations of tincture of iodine into the sinuses. The principal effect appeared to be the sclerosing action of the locally used iodine. When practicable this treatment seems worthy of trial.

Plasma Protein Concentration After Hemorrhage—Beattie and Collard determined the movement of plasma protein into the blood stream during the first two hours after a known quantity (20 per cent) of blood had been withdrawn from the circulation of cats. After hemorrhage the restoration of blood volume was independent of the restoration of plasma protein. Restoration of both concurrently would imply considerable protein stores. The speed of blood volume restoration in the cat apparently outstrips the rate of plasma protein movement into the blood stream. In man even after large hemorrhages (1,150 cc) the plasma protein concentration can remain unchanged, although blood dilution is proceeding rapidly. Blood transfusion at varying times after hemorrhage was followed by movement of plasma proteins out of the circulation within one hour of completion of transfusion. Plasma transfusion after hemorrhage was followed by plasma protein movement out of the circulation within one hour of the completion of the transfusion. The rate and amount of plasma protein movement into the circulation were independent of the amount or rate of bleeding, the amount or rate of dilution by fluid from the tissue spaces and the blood pressure changes. The amount of plasma protein contributed to the blood, therefore the plasma protein concentration at any time after hemorrhage (provided no food containing protein was consumed), was probably dependent on the state of the plasma protein stores outside the circulation.

Circulatory Overloading After Rapid Intravenous Injections—The effect of the rapid intravenous injection of up to 2,000 cc of saline solution, serum and blood to a few persons on the venous pressure and other cardiovascular measurements are reported by Sharpey-Schafer and Wallace. The injection was given to subjects without cardiovascular disease at rates of 54 to 168 cc per minute. The venous pressure was raised up to 11 cm of water, when considerable of the injected fluid was retained in the circulation, this was indicated by the fall in hemoglobin. Roentgenograms showed an increase in the diastolic size of the heart, enlargement of the pulmonary arteries and prominence of the vascular markings in the pulmonary fields. Vital capacity was diminished, but there was no evidence of pulmonary edema. In spite of the rise of venous pressure, many subjects had no increase in heart rate. Of 12 subjects 4 showed electrocardiographic changes of right heart stress.

There was a rapid fall of venous pressure to normal on ceasing injection, except in 1 subject given blood. Evidence suggests that the peripheral and pulmonary capillaries and veins dilate to accommodate the increased blood volume. When the blood volume was first reduced by a large venesection, saline solution or serum injected in similar amounts and at similar rates caused little or no rise of venous pressure.

Photosensitivity of Sulfonamides—The treatment with the sulfonamides of many ambulant and inpatients in an open air tent hospital in the Middle East has provided Park and Platts an opportunity to observe eruptions due to photosensitization. During twelve months 486 patients received sulfanilamide and eruptions developed in 21 of them. 309 received sulfapyridine, and eruptions developed in 6. The eruptions have been divided into two groups: those limited to parts exposed to the sun during chemotherapy and those which were maximal on exposed parts but also affecting other parts of the body. Sulfanilamide was responsible for 16 of the 17 milder cases. Five each of the more severe cases were caused by sulfanilamide and sulfapyridine. The greater incidence with sulfanilamide may have been due to the fact that only ambulant patients received sulfanilamide. About half of the cases occurred during July and August. Photosensitivity occurred in eight to ten days of administration. Two patients became photosensitive two days after chemotherapy was stopped. It appears that patients given sulfonamides for more than six days are potential victims. That the presence of melanin was a protection against the eruptions is supported by the following facts: About one third of the patients were subjects who sunburn easily, the bronzed parts of the body tended to be affected less often than the other parts and no eruption was seen in Maoris, who comprised about 100 of the patients. The following parts were affected in order of severity: those exposed to the sun during chemotherapy, parts exposed to the sun in the past, pressure points and parts always kept covered. The most common lesions were erythematous papules in a morbilliform or roseoliform pattern which became confluent. Itching varied. Less common lesions were edema, urticaria, vesication, pustulation and desquamation. Drug fever and other toxic effects accompanied 12 cases. Most of the rashes subsided in two to four days. By avoiding further exposure to sunlight, 6 patients completed their courses of chemotherapy and 3 had further courses later without ill effects. In the milder cases a rash was no indication for discontinuing chemotherapy.

Dysentery and Diarrhea in Wartime P. H. Manson Bahr—p. 346

Estimation of Hemoglobin—Clegg and King believe that the following criteria are required for a satisfactory method of estimating hemoglobin. The method must measure total pigment with a reasonable degree of accuracy and yet be simple enough to be employed in a laboratory in which many determinations are performed daily. The measurement must be in simple standards, and nontoxic reagents should be used. The most likely procedure appears to be the alkaline hematin method of Wu. The method eliminates the errors which arise in the acid hematin procedure due to lipids, the colloidal nature of acid hematin and the presence of inactive hemoglobin. The authors tested its reliability by preparing sixteen samples of crystalline hematin from ox and human bloods and determined the iron content of each. They found the specific extinction coefficients to agree closely; the intensity of color was proportional to the concentration of hemin iron and impurities failed to influence the color. Several forms of hemoglobin occurred in normal blood, some of which were resistant to alkali denaturation. Whatever the proportion of alkali resistant hemoglobin in a sample a 1 in 100 dilution in decinormal soda placed in a boiling water bath for five minutes will convert all the hemoglobin into alkaline hematin. Similar treatment converts all inactive hemoglobin into alkaline hematin. The color is not significantly influenced by the amount of lipid or plasma present in the sample. Determinations of hemoglobin in blood samples based on the assumption that 1 mg of hemin iron in the standard

was equivalent to 1 mg of hemoglobin iron in the test yielded results uniformly about 30 per cent higher than determinations based on the oxygen carrying power of the same sample. Solutions prepared from hemin and blood gave colors whose absorption curves differed slightly in the red portion of the spectrum.

Combined Inductopyrexia and Chemotherapy for Gonorrhea—A few cases are reported by Batchelor and his collaborators to illustrate the value of induced pyrexia and chemotherapy for intractable or protracted gonorrhea. Their routine is practically 100 per cent successful. On the day preceding the hyperpyrexia 6 to 8 Gm of intravenous soluble sulfapyridine is given in divided doses, 2 Gm in 30 cc of sterile distilled water. On the morning of treatment 2 Gm of sulfapyridine is given orally. The minimum hours of fever at a temperature of over 106 F should be eight. During the fever a further 6 to 8 Gm of sulfapyridine orally or intravenously may be administered when necessary. Chemotherapy should be continued for five days. Local treatment after the pyrexial therapy is not indicated unless secondary urethral infection is present.

Low Pressure Phase of Blast—Latner carried out experiments on mice to determine the effects, if any, of exposure to an exceedingly short duration of low pressure, similar to that occurring with blast. Approximately half of the animals died instantly or within a short period. At necropsy typical intra-

thoracic and extrathoracic blast lesions were observed. In the treatment of blast injuries of the lung, immobilizing the chest with a bandage might prevent further pulmonary bleeding. It seems possible that the pulmonary lesions of blast are primarily due to overstretching from overinflation of the pulmonary substance during the low pressure phase and at the end of the high pressure phase by the elastic recoil of the thoracic wall. These factors would tend to be additive. For the prevention of blast injuries of the lung, tight elastic bandages around the chest or a jacket are suggested to prevent overinflation.

Bronchiectasis Without Disability—Martin and Burridge discuss data from 25 examples of bronchiectasis seen during two years in Emergency Medical Service hospitals among serving soldiers. Most of them were graded A1 in the army, this emphasizes that even extensive bilateral disease can occur among men of healthy appearance and with little incapacity. Many of the cases were detected as a direct result of the war and the facilities it provides, as in peacetime many would not have sought or gained admission to hospitals. Service life may have brought out symptoms which might otherwise have remained dormant for some time. Cough and sputum were the presenting symptoms in 23, dry pleurisy in 1 and evening pyrexia in 1. A history of slight hemoptysis was furnished by 7, mild night sweats by 6 and loss of weight by 4. Although some patients had bilateral bronchiectasis or considerable unilateral sacular disease none appeared toxic or ill nourished. Physical signs in the chest varied considerably in different patients and in the same patient from time to time. Impairment of percussion note, diminished entry, persistent coarse or medium rales and scattered rhonchi were commonly found in various combinations, while pleural friction over the affected area of the lung was audible and palpable in 4. The histories and symptoms made a diagnosis of bronchiectasis probable and prompted bronchography. Plain roentgenograms enabled bronchiectasis to be definitely diagnosed in some and suspected or excluded in others. Bronchography was essential for demonstrating the exact extent of the disease, even when recognized in the plain film, and for proving the presence or absence of bronchiectasis in doubtful cases. The oral technique for bronchography was preferred to the nasal or the intratracheal technique. Bronchiectasis, sometimes gross, was fairly common in patients of apparently healthy appearance and little physical incapacity. Such patients are rarely seen in general hospitals in peacetime. Prognosis can not as yet be discussed, but the expectation of life for patients with bronchiectasis in general may be somewhat pessimistic. Many of the patients gave histories of diseases of the chest in childhood which might have initiated the bronchiectasis, yet the men were still apparently fit enough twenty years later to be graded A1 in the army and to have had little incapacity in civilian life. Some of the patients might—save for bronchography—have passed through life with no more serious diagnosis than chronic bronchitis.

Pernicious Anemia of Pregnancy—Miller and Studdert encountered 23 cases of pernicious anemia of pregnancy during the last five years. Only a few were suspected by the outside physician, and many patients were permitted to become dangerously ill before investigation and treatment were instituted. The disease is a macrocytic hyperchromic anemia occurring late in pregnancy or in the puerperium. It differs from pernicious anemia in that hydrochloric acid may be present and in that the prognosis for complete cure is better, subacute combined degeneration does not occur. The 23 women responded to specific therapy, and in 14 it was subsequently discontinued. Dietary deficiency and vomiting were important etiologic factors. Free hydrochloric acid was present in the gastric juice of 18

women, in such cases a preparation of autolyzed yeast added to a good mixed diet may be sufficient treatment. When there is chlorhydria or when the autolyzed yeast fails, either refined or crude liver extract by injection or if even this fails liver by mouth is indicated. Some degree of iron deficiency often becomes apparent during therapy.

Fate of Transfused Erythrocytes—The fate of transfused erythrocytes has been determined with the aid of erythrocytes of different blood groups, by means of stained blood or by transfusion of blood from patients with polycythemia to those with severe anemia. The most important methods are those which utilize group specific characteristics. These agglutination methods according to Willenegger, have the disadvantage that the serologic process of agglutination is not complete. He conceived the idea of utilizing group specific hemolysis rather than agglutination for the demonstration of donor erythrocytes. Hemolysis is a serologic reaction which, in the presence of adequate activity of the hemolysins, is always complete. Voronoff had made this suggestion before him. To secure a serum that contains sufficiently active hemolysins is the main difficulty of the method. Whereas Voronoff employed a rather dangerous method to obtain this end, the author observed that the hemolysin of O blood, which has a high anti A agglutinin titer (1,024 or more) is sufficiently active to be used for the experiments. Such O donors are not at all rare. The author transfuses fresh or converted O blood to a person with A blood. The fate of the donor corpuscles in the recipient's blood is periodically investigated. The gradual decrease in donor erythrocyte values is recorded in curves, which exhibit a fairly regular decline. It was possible to detect donor erythrocytes in the recipient's blood one hundred to one hundred and thirty days. The use of the group specific hemolysins yields much more exact results than do the agglutination methods.

Subperiosteal Resection and Plugging of Bone Defects for Osteomyelitis—According to Henschen a chronic osteomyelitic focus represents a constant source of danger, and its removal therefore constitutes the basic problem in the treatment of osteomyelitis. He describes a new method which he employed in several cases of fracture osteomyelitis. After the limits of sclerotization have been ascertained, subperiosteal removal of bone is accomplished with a Gigli saw, care being taken not to damage the periosteal coat and the tendinous fibers entering into it or radiating from it. The resected, extremely hard bone is cut up with saw and scissors, is boiled for twenty minutes in a 0.1 per cent solution of salicylic acid and is ground up in a bone mill, or the coarsely fragmented bone is sterilized dry for the same period and is then ground up. The wet or dry bone meal is placed into the subperiosteal space after the space has been irrigated with a 1 per cent solution of hydrogen peroxide and after careful hemostasis. The periosteal coat is then closed with button sutures. The proper length and alignment of the bone is secured by Lane plates or by Judet's screw fixation. In 2 cases in which this method was employed, solid consolidation with proper length and alignment was obtained. There was no formation of fistulas. The sterilized bone meal serves as building material and exerts a stimulus on the osteogenic tissues. The osteogenic stimulus may be intensified by mixing the bone meal with a sterile 33 per cent solution of bone gelatin, thereby forming a paste that forms a true "succus ossificus." The bone meal should not be mixed with iodoform or sulfathiazole, because this would impair the biologic effect.

New Treatment of Pulmonary Tuberculosis—A case of pulmonary tuberculosis, in which pneumothorax induced an interstitial emphysema and caused shrinkage of a cavity, suggested to Rona that respiration under negative pressure could accomplish a similar result. He effected this type of respiration by means of a suction apparatus with a mouth piece, the nose being closed with a clamp. The apparatus is connected with a water manometer and is equipped with a regulatory device. Cavities communicating with a bronchus may be emptied in this manner. The negative manometer pressure varies between 5 and 8 cm of water for expiratory and between 9 to 12 cm for inspiratory pressure. The negative pressure respiration is employed daily for months. The daily treatment is gradually increased up to four two hour periods. The patients become rapidly accustomed to the negative pressure breathing. The author describes 11 cases, in only 1 of which has the method failed. New, thin walled cavities are more responsive to this therapy than old cavities. The method is not effective where extensive areas of lung have been destroyed and where cavities are not surrounded by healthy pulmonary tissue. Apical cavities surrounded on three sides by a rigid wall are likewise unsuitable for this treatment. The treatment may prove helpful also in some nontuberculous pulmonary lesions such as pulmonary abscess, bronchiectasis, certain cases of chronic bronchitis, laryngeal disease, whooping cough and in the after treatment of pleurisy.

Biology of Human Spermatozoa—Joel points out that opinions regarding viability of human spermatozoa in the vagina differ greatly, some authors estimate it to be from seven to eight days, others from twelve to seventeen days and still others only a few hours. Belonoschkin's studies indicate that the duration of viability is only forty-five minutes. Joel made studies on 8 women who requested treatment for sterility. Results of his studies tally with those of Belonoschkin. The spermatozoa were still viable in the vagina forty-five minutes after coitus but failed to show motility after sixty-five minutes. The author agrees with Belonoschkin that the vagina cannot be regarded as a receptaculum seminis. This role must be ascribed to the cervix where the spermatozoa remain longest. It has been found that the spermatozoa remain twenty-five hours in the body of the uterus. The orgasm plays some part in the passive transmission of the spermatozoa and in the conception. The tubes contain only dead spermatozoa after twenty hours, according to Hoehne. Joel concludes on the basis of these and earlier investigations that human spermatozoa remain viable in the female organism up to forty eight hours.

Functional Alterations of Pancreas in Duodenal Ulcers—According to Castex and his associates, lesions of the pancreas often concur with those of the stomach, duodenum, liver and the biliary passages. Insufficient attention is paid to functional disturbances of the pancreas. The course of a

ulcer is often accompanied by symptoms which direct attention toward pancreatic involvement such as pain on the left side, intestinal disturbances in the form of an enteritis, gastroenteritis or flatulent dyspepsia appearance of feces which indicate a mild lack of fat digestion, a transitory glycosuria, loss of appetite alternating with voracious hunger, and psychic disturbances such as anxiety, nervousness, asthenia and restlessness. They performed Wohlgemuth's test on the blood and urine in 40 cases of duodenal ulcer and in some cases they also studied the lipase in the duodenal contents. Pancreatic involvement was detected in 15 of the 40 cases, or 37.5 per cent. They are even more frequent in acute ulcers and in the acute flare-ups of chronic ulcers with edema, hemorrhage and pain. The physiopathologic relationship between the duodenal and pancreatic processes may be explained by the anatomic contiguity, functional association ascendant canalicular infection, hematogenous metastasis, direct lymphatic passage (demonstrated by Bartels) and allergic conditions present in some cases of ulcer.

*Volkmann's Dry Caries of Shoulder Osteoarthritis. A. E. Bail, M. F. Corsellas and E. J. Molina Mascias —p. 578

Volkmann's Dry Caries—Bail and his collaborators report 7 cases of tuberculous osteoarthritis of the shoulder in adults observed for several years. Early in the course of the disease there are but few symptoms and pain is moderate. Later, there appear fever and acute pain, the articular movements are gradually restricted and atrophy of the scapular muscles, especially of the deltoid, rapidly progresses. Majority of the patients remain in good general health for a long time. Some complain of toxic symptoms. The first tuberculous lesions in the bones appear in the roentgenograms when they have reached about the size of a large pea. All lesions are situated at the periphery of the head of the humerus and in the humeral epiphysis. In the advanced period the interarticular fissure is widened when there is hydrarthrosis and narrowed in the absence of it. Hygienic dietetic regimen, heliotherapy and climatic therapy at the seashore are indicated. Orthopedic treatment is indicated in children. In adults orthopedic treatment alone is not sufficient. It is resorted to as a preoperative therapy. The joint is immobilized in a cast for a time during which the patient has the proper general therapy. Extra articular arthrodesis is successfully performed.

*Polyneuritis Due to Whooping Cough. J. C. Santa Maria and Y. Besedovsky —p. 16

*Massive Doses of Vitamin D in Therapy of Rickets. Gloria Lovell —p. 19

Polyneuritis Due to Whooping Cough—Santa Maria and Besedovsky report a case of polyneuritis and paralysis of the legs developing in an infant in the course of whooping cough. The Wassermann reaction was negative and the cerebrospinal fluid was normal. The patient was treated with massage of the legs and vitamin B₁. The disease pursued a favorable course and terminated in a recovery within three weeks. The paralytic symptoms were caused by a multiple neuritis due to localization of the virus in certain peripheral nerves.

Massive Doses of Vitamin D₂ in Rickets—Lovell administered large doses of vitamin D in 5 cases of acute rickets in infants of very poor families. The substance was given by mouth in daily doses of 50,000 international units for ten consecutive days or by intramuscular injection of 200,000 international units every other day up to a total of 600,000 international units. Symptoms of intolerance did not appear. The immediate results were as good as those of the classic therapy of rickets but more rapid. The disease recurred in 1 of the patients, who probably was resistant to the substance. The author advises giving small doses of the vitamin for a long time after discontinuation of the therapy, especially in winter, in order to maintain the good results of the large doses.

Delusions of Schizophrenic Patient. G. Schmidt —p. 570
Sleeping of Night Shift Workers. M. Breuninger —p. 591

Hereditobiologic Evaluation of Postinfectious Psychoses—Observations on 37 patients convinced Enke that hereditary endogenic factors play only a subordinate role in postinfectious psychoses. The number of patients with a tendency to psychotic reactions is large. This tendency may consist in physical or nervous exhaustion, constitutional deficiency or endocrine disturbances. In some cases there exists also a temporary tendency to a psychosis, that is, repeated and severe exogenic lesions may cause a symptomatic psychosis in entirely normal persons. Repeatedly observed changes in the cerebrospinal fluid of patients with postinfluenzal psychoses indicate an organic reaction of the central nervous system to the infectious virus. These organic lesions may be partly responsible for the postinfluenzal psychoses. The course of postinfluenzal psychosis is usually favorable, but permanent injury is not impossible and termination into such a permanent injury is not necessarily a proof of the endogenic character of a psychosis. The author concludes that the majority of postinfectious psychoses which develop in the absence of a hereditary predisposition are exogenic in origin regardless of whether their symptomatology is predominantly exogenic or endogenic. In the presence of a hereditary predisposition, however, postinfectious psychoses with an endogenic symptomatology are usually endogenic in nature. Schizophrenia that develops after an infection can be regarded as endogenic only when the psychosis terminates with a schizophrenic defect or when a further not exogenically elicited schizophrenic attack can be demonstrated. In such cases there frequently exists proof of hereditary predisposition or of schizoid characteristics in some of the relatives. Since the postinfectious psychoses with cyclic characteristics, in contradistinction to schizophrenia usually regress without residual defects, this indicator of endogenicity is absent. Thus there must be clear signs of hereditary predisposition to manic depressive psychosis if a postinfectious circular psychosis is to be identified as endogenic.

Epidemic Encephalitis and Veterans' Compensation—In reviewing testimonies in compensation cases for post-encephalitic parkinsonism, Schnitzer repeatedly encountered the statement that a symptom free interval of fifteen and more years existed between the acute onset of epidemic encephalitis and the appearance of postencephalitic parkinsonism. He raises the question of whether such a symptom free interval occurs with sufficient frequency to be acceptable as a factor in the evaluation of epidemic encephalitis. His observations in 67 cases did not reveal a single one with a symptom free interval of ten years' duration. He regards long symptom free intervals between the acute stage of epidemic encephalitis and parkinsonism as extremely rare. He concludes that there have been cases with a symptom free interval between the acute and chronic form of epidemic encephalitis. A case reported by Brünner indicates that this interval can be extremely long. However, reports by Leonhard, von Witzleben and Tyndel are not sufficient proof that such symptom free intervals are frequent. The symptom free interval is important for the physician who renders expert testimony in compensation cases only if the acute infection was typical and established beyond a doubt. Compensation for service injury should be recognized only when the patient with postencephalitis had the acute infection during the period of service. If during the war he had only an influenza like or a latent acute infection, the probability of a causal connection of the parkinsonism with the acute disorder is to be confirmed only if pseudoneurasthenic symptoms can be traced back to this acute disorder and it thus can be proved that it has been an atypical, acute epidemic encephalitis.

Book Notices

Industrial Psychology By Joseph M. Latham Ph.D. Professor of Industrial Psychology, Purdue University, Lafayette, Indiana. Cloth. Price \$1.65. 1 p. 386 with 96 illustrations. New York: Praeger, Inc. 1942.

Industrial psychology is too little known and understood by the medical profession. It supplements industrial physiology and hygiene by surveying aptitudes, capacities, interests and attitudes. The present volume is a rather academic work apparently intended for psychology and engineering college students and not aimed directly at the medical profession. It gives a fairly good general picture of the methods of testing employees in order to place the right shaped peg in the appropriate hole. Some attention is also given to interpersonal relationships such as foremanship and some of the factors which go into developing a favorable attitude toward the employer. Much of the material discussed covers specific tests which have been constructed and adequately standardized for some special selecting procedures. Some consideration is also given to the matter of properly training employees. Of most importance to industrial physicians, however, are the chapters on visual problems of industry and on work, fatigue and efficiency. The material covered in the chapter on vision shows that many of the visual standards previously conceived as being accurate by the ophthalmologist fluctuate and need to be dealt with by directing the eye specialists' attention directly to the job in hand rather than to the general correction of visual errors. The effect of age, specific job requirements, eye wear, classifications and retest of vision are among some of the interesting topics dealt with in this chapter. The atmosphere of the book is distinctly peacetime. Stress is laid on selecting the best worker for the best job and on the readjustment of employees who are deficient to begin with in order to make them superior workers. Whereas the wartime attitude of industrial psychology is to develop placement procedures which will make the hitherto inadequate employee a useful contributor to production. There are two appendices dealing with statistical matters, and a third which gives a list of publishers of aptitude tests.

The Toxicity and Potential Dangers of Toluene with Special Reference to Its Maximal Permissible Concentration By W. F. von Oettingen and others. From the Division of Industrial Hygiene, National Institute of Health. Prepared by Direction of the Surgeon General, Federal Security Agency, U. S. Public Health Service, Public Health Bulletin No. 271. Paper. Price 10 cents. 1 p. 50 with 20 illustrations. Washington: D. C.: Dept. of the Interior, Government Printing Office, 1942.

On the basis of evidence presented in this pamphlet, the maximal permissible concentration of toluene in air is put at 200 parts per million for eight hours' exposure. Since some variation in muscular coordination is produced in human subjects at this level, further reductions are indicated wherever specific or unusual accident hazards exist. The authors conclude that toluene is less toxic than benzene in respect to the hemopoietic system and less toxic than carbon tetrachloride on the liver. Other effects were noted, such as pulmonary and kidney irritation, especially on exposure to higher concentrations. Routes of assimilation and excretion are described. If concentrations are held at or below the maximal figures quoted in this report, the authors feel that untoward effects are not to be expected.

Formulary and Handbook The Johns Hopkins Hospital. Edited by John C. Krantz Jr., Secretary of the General Committee of Revision of the United States Pharmacopoeia. Cloth. Price \$2. Pp. 233. Baltimore: John D. Lucas Company, 1942.

This booklet is just what it purports to be. It is prepared to familiarize the staff of the hospital with the various medications that are available from the pharmacy. The basis of admission of substances to the formulary are said to be therapeutic efficacy, simplicity and availability. The booklet is exceedingly practical, and one finds few of the complex formulas which in a previous generation would have been the chief items in such a list. There is still, however, a complicated formula for a douche powder, and innumerable complicated formulas are used in diseases of the skin. A casual survey shows no preparations from the National Formulary and, indeed, relatively few from any sources except the United States Pharmacopoeia and New and Nonofficial Remedies.

A Textbook of Gynecology By Arthur Hale Curtis M.D. Professor and Chairman of the Department of Obstetrics and Gynecology, Northwestern University Medical School, Chicago. Fourth edition. Cloth. Price \$8. Pp. 723 with 401 illustrations chiefly by Tom Jones. Philadelphia & London: W. B. Saunders Company, 1942.

The qualities responsible for the popularity of Curtis's textbook, sustained for more than a decade, are again apparent in this edition. Revision every four years keeps the volume abreast of the times, and the period is also sufficient for the appraisal of novelties, diagnostic and therapeutic. With remarkable efficiency available material has been assimilated. However, in the evaluation of new concepts and new procedures greater boldness would be justified. When passing judgment on the work of others, reticence, while becoming, is neither desirable nor necessary in this instance. The author's recognized fairness of mind, his grasp of the subject, his intimate experience of recent contributions to theory and practice, all combine to equip him as an expert—a very slight suggestion, to be sure intended to encourage unequivocal verdicts more generously in future editions. None the less, the book meets the requirements of medical students exquisitely and, by the same token, offers men in practice for a number of years a refresher course, an ambition of many whose duties keep them at home.

Here the capital chapters of gynecology have been refurbished skilfully. Sections on menstruation and its abnormalities, together with pertinent topics introduced logically elsewhere in the text, fill a hundred pages. The flux and change of endocrine teaching receive ample consideration, correctly critical of commercial products indiscreetly advertised.

The therapy of gonorrhea and of puerperal infection duly stresses the sulfonamide compounds, preferably sulfathiazole.

Myomas, with causation as yet undetermined, invite speculation, notably with respect to treatment. The author would limit irradiation to small fibroids and to women toward the end of the childbearing period or thereafter.

Cancer of the cervix may be cured in 56 per cent of the cases if recognized early, but in only 5 per cent when diagnosis has been delayed until a late stage. The choice between radical hysterectomy and irradiation remains a source of lively dispute. Apparently the advocates of high voltage roentgen therapy are gaining ground steadily. Cancer of the body of the uterus is another matter. Scant room there for argument. Whole hearted commendation has been won by the New York Memorial Hospital technic: preliminary intensive irradiation followed by curettage to confirm the diagnosis, and ten days later abdominal hysterectomy with removal of the tubes and ovaries.

Displacements and relaxations, the title of a valuable chapter, are illustrated lavishly. The narrative reflects the author's devotion over many years to the study of anatomic and mechanical details concerned with normal support of the pelvic organs. His well known monographs on this subject reached conclusions which shape the course of the operative technic he advocates in all a very distinguished service.

A short section on sterility in women, more valuable because compact, reviews the causes of infertility, the diagnostic methods currently employed and subsequent management, often tedious. The paragraph dealing with surgical procedures devised to bring about sterilization conveys a false sense of security. No matter what the procedure, failure occasionally will be the sequel, even with the Madlener operation. Such a possibility ought to be mentioned, at least.

Most impressive in this edition is the rewritten section on ovarian tumors. The literary work involved has been done efficiently. On the other hand, the practical aspects of the subject are marred by the absence of a classification, confessedly impossible on the basis of either embryology or histology. So another criterion must be sought. Inspiration for the project is not wanting. The present achievement of a morphologic classification of bony pelvis conforming with x-ray findings and supplanting the older grouping along developmental lines should bring encouragement.

Mere enumeration of ovarian neoplasms, the plan adopted here, unjustly coordinates these tumors—promotes a distorted view of their relative clinical significance.

Admittedly, it serves a good purpose to discuss at considerable length dysgerminoma (granulosa cell, arrhenoblastoma, Brenner tumor, mesonephroma and other types on which pathologic

interest centers at the moment) It clarifies the nature of these mysterious growths and thus will lead more frequently to immediate identification However, that they will ever become more than curiosities is doubtful Certainly they will never be prominent in the day to day practice of gynecology While one reads the descriptions of these rare, peculiar tumors—and indeed time and again throughout the book—there is an awareness of the author's master hand at the difficult art of clear medical exposition

Food and Drug Regulation By Stephen Wilson Introduction by Walton H. Hamilton Cloth Price \$3.25 Paper Price \$2.50 Pp 177 Washington D. C. American Council on Public Affairs 1942

The story contained in this book, vividly and interestingly told, concerns the history of federal efforts to protect consumers from misbranded and adulterated food and drugs As pointed out by the author federal legislation on the problem has been a long drawn out struggle beginning with the first general proposal introduced in Congress in 1891 by Senator Paddock of Nebraska and culminating for the present at least in the enactment of the Food Drug and Cosmetic Act of 1938 Between 1891 and 1906 each Congress was asked to enact legislation to afford consumers some modicum of protection but it was not until the latter year after decades of education and agitation, that an insistent public opinion finally resulted in the passage of the first comprehensive federal law dealing with the problem The important part that Dr. Harvey Wiley, described by the author as 'easily the outstanding figure of the long crusade for pure food and drugs,' assumed in the struggle and the strenuous opposition of the traffickers in nostrums are portrayed in detail Loopholes and defects in the 1906 law were recognized in the early days of enforcement, and many attempts were made to improve the act Year after year recommendations were made to Congress but nothing came of them This inaction resulted, the author thinks from a lack of public concern and from the continued opposition of the same forces which had delayed passage of the law for so many years The concluding chapters of the book are devoted to the active campaign for new legislation that began in 1933, to an analysis of the act of 1938 that eventuated from that campaign and to a discussion of the purposes and consequences of food and drug legislation The final paragraph in the book is provocative "Perhaps the answer to the pure food and drug problem lies in consumer education Certainly that field has been badly neglected And certainly the consumer has much at stake An official of the Federal Trade Commission has estimated the amount taken from consumers annually through the sale of merchandise fraudulently advertised at \$500,000,000 Sound consumer education will inevitably result in an extension of sound food, drug and cosmetic legislation"

Pulmonary Tuberculosis and Its Treatment By Hims Jacob Ustvedt M.D. First Assistant Physician to the State Hospital Oslo Translated by A. L. Jacobs M.R.C.P. With a foreword by W. D. W. Brooks D.M. F.R.C.P. Cloth Price 25s Pp 252 with 56 illustrations London John Bale Medical Publications Limited 1942

In introducing this textbook in England, Brooks points out that it presents an opportunity to study the disease from a fresh point of view The publication sets forth the Norwegian attitude to the subject in a concise and eminently readable form Some of the views put forward by Dr. Ustvedt diverge from the orthodox as we understand it These opinions are advanced, however, with impartiality, the evidence being cited on which they are based The book originated from a series of lectures to medical students at the University of Oslo Emphasis is laid on the practical and clinical aspects of the subject, but the theoretical aspects are not neglected During the past ten years there has been intensive research into many tuberculosis problems in Scandinavia, and the author aimed to make some of the results of this work known to the English speaking medical world, particularly the work of Olaf Scheel and Johannes Heimbeck The contents include five chapters on tuberculous infection, progressive pulmonary tuberculosis (phthisis), milary tuberculosis, treatment and prophylaxis Aside from the usual considerations, the author includes tuberculin tests, laboratory tests, differential diagnosis, complications, and tuberculosis and life insurance The book is interesting to the American physician because it develops mainly around continental European views which are frequently not clearly defined in American

works The immune conception bases on a close binding with actual presence of infection dating from the classic Koch experiment, and thus also BCG is justified for its relative value In phthisis the primary and secondary changes are stressed and various types of solitary foci and cavities are elucidated Collapse treatment may not be needed in a large group of cases, but with evidences of cavity this is the only valuable form of active treatment Artificial pneumothorax is still established on an empirical basis and is primarily mechanical The chief indication for thoracoplasty is tuberculous cavities which cannot be made to collapse by pneumothorax treatment Sanatoriums have gradually changed from peaceful backwaters of conservative therapy into tuberculosis hospitals where active methods of treatment are extensively applied As a subsidiary to active therapy general treatment has its value At present there is general agreement that there is no special diet which has a specific curative effect on tuberculosis Thus Ustvedt presents a book containing many of the modern rationalities on tuberculosis but highly punctuated with the recent Scandinavian views which merit reading The publishers of this English edition present it on a good grade paper (5½ by 8½ inches) suited to taking the illustrations and for convenience in carrying and filing

High Polymers A Series of Monographs on the Chemistry Physics and Technology of High Polymeric Substances Editorial Board H. Mark F. O. Krueger and C. S. Wilbiss Volume IV Natural and Synthetic High Polymers A Textbook and Reference Book for Chemists and Biologists By Kurt H. Meyer Ph.D. Professor of Organic Chemistry University of Geneva Geneva Switzerland Translated by L. E. R. Helen Ph.D. Cloth Price \$11 Pp 600 with 150 illustrations New York Interscience Publishers Inc. 1942

This book is volume IV in a series of monographs on the chemistry physics and technology of high polymeric substances It appeared originally as the second volume of a two volume work in German on the structure of natural, organic high polymers The author attempts in this volume to give a systematic account of the entire field of natural and synthetic high polymers both inorganic and organic After a general discussion of the methods employed in the study of high polymers, the author considers inorganic high polymers and high polymeric hydrocarbons, including rubber and related substances About one third of the book is devoted to cellulose, starch, gums and other polysaccharides The author then discusses proteins, including globular and fibrillar proteins enzymes and virus proteins The last portion of the book deals with the properties of solutions of high polymers, films and membranes and, finally, the molecular structure of plant and animal tissues Besides containing a great deal of valuable information, the book emphasizes a point of view which will be new and perhaps stimulating to most biologists This point of view and its value to the biologist may be best indicated by quoting directly from the translator's preface The common meeting ground of chemists and biologists in high polymer chemistry is that of morphology Since the day when, as a result of the development of x-ray analysis, chemical formulas ceased to be symbols on paper and became models in three dimensions the chemist has become more and more accustomed to think in terms of what may be called morphological chemistry To the biologist, who observes that both shapes and properties of cells and cell components reflect their molecular organization, it seems likely that morphological chemistry may prove to be the chemistry of morphology It is for him now to consider biological structure and organization in their high polymer guise"

Traumatic Surgery of the Jaws Including First Aid Treatment By Kurt H. Thoma D.M.D. Professor of Oral Surgery and Brackett Professor of Oral Pathology Harvard University Boston Cloth Price \$6 Pp 315 with 282 illustrations St. Louis C. V. Mosby Company 1942

This book is intended as a guide to surgeons and dentists who are confronted with injuries of the jaws There are ten chapters, covering first aid treatment, examination of the patient, treatment planning, facial and oral wounds, traumatic injuries of the teeth, fractures of the mandible, fractures of the maxilla, traumatic injuries of the condyle and mandibular joint, deformities caused by traumatic injuries, nursing and diet In the management of fractures of the jaws the author's wide personal experience is well reflected In addition he describes most of the newer methods of fixation, such as the intraoral pin fixation

of Berry and the various extraoral skeletal fixation plans based on the Roger Anderson principle. Mention is not made of the Kirschner wire transfixation method is described by Barrett Brown. In fracture dislocation of the neck of the condyle of the mandible, Thomas advocates the open method of reduction and fixation. This is contrary to the opinion of most authorities, who feel that conservative methods yield sufficiently satisfactory results in the vast majority of cases without running the risks attending the open method. The complications and deformities resulting from traumatic injuries of the jaws are well covered with the exception of restoration of losses of substance by bone grafting, which receives no attention at all. This important omission should be corrected in a future edition, since approximately 10 per cent of gunshot fractures of the lower jaw result in nonunion requiring bone grafting. A complete bibliography is appended. Dr Thomas has presented a useful contribution for those interested in this special field of surgery.

Binoocular Imbalance. By Margaret Dobson M.D. Cloth. Price 60s. 6d. 1p. 76 with 13 illustrations. London: H. K. Lewis & Co. Ltd. 1912.

The author believes that binocular balance depends on the correct relationship between convergence and accommodation. The technique of examination of the extraocular muscles is described in minute detail, and the standard for average deviations is presented as:

lateral adduction 18^{Δ} out cyclophoria 5^{Δ} near point 36^{Δ}
abduction 5^{Δ} in cyclophoria 2^{Δ} near point 36^{Δ}
vertical supraduction 15^{Δ} infraduction 2^{Δ}

A discussion of heterophoria and its therapy stresses exophoria as the commonest type, due to general debility, retractive error, insufficient convergence at the near point, and toxins. It is treated by a full static correction of the refractive error and orthoptic exercises (base out) to increase the fusional convergence. A search for the focus of infection in the antrum or ethmoid, is made in case of toxic exophoria. Presbyopia occurs when the amplitude of accommodation falls below 45 diopters. Although convergence at the reading point is a fixed quantity (18^{Δ}) the accommodation is variable depending on the angular measurement of the visual angle. In presbyopes two thirds of all the exophoria at the near point in excess of 10^{Δ} is corrected in the glasses. A patient having 16^{Δ} exophoria at the reading distance will require 2^{Δ} base in before each eye for comfort and increased visual acuity. For the beginner as well as the experienced private practitioner in ophthalmology this book offers an excellent study of the tests and therapy of muscle imbalance of the eyes.

The Minnesota Multiphasic Personality Schedule. By Starke R. Hathaway M.D. Associate Professor of Psychology and J. Charles McKinley M.D. Professor of Neuropsychiatry, University of Minnesota. Minneapolis. With 50 Test Cards, One Manual, 7 Scorers, Transparencies and 50 Record and Profile Sheets. Paper. Price \$15. 1p. 31. Minneapolis: University of Minnesota Press. 1942.

This is a psychometric device useful in personality evaluation by psychiatrist, personnel worker or psychologist. It is particularly devised to bring to light persons with significant neurotic or psychopathic tendencies. The test consists primarily of five hundred and fifty statements, each printed on a separate card, covering a wide variety of subjects and interests. Attitudes about health, religion, sexual and general social attitudes and occupational interests indicate the range of interests touched on. The test is easy to administer, since the subject has merely to sort the cards into the three categories true, false or cannot say. The sorted cards are tabulated so as to provide a basic record, which may be scored at present by keys which measure hysteria, depression, hypochondriasis, psychopathic personality and masculinity-femininity. Additional keys are being developed, e.g. a key for paranoia. The standard data were obtained from studies of 700 normal adults and from 600 patients who were in a psychiatric hospital.

This personality schedule, in the hands of properly trained psychiatrists and psychologists, would appear to be of considerable usefulness when large numbers of persons must come under observation, as in industry. Doubtless disturbed persons can be sifted out by proper use of devices such as those here offered. The fact that the schedule is easy to administer should not be permitted to lead to its use by persons untrained in psychiatry

or psychology. The schedule is not intended to do more than help identify disturbed persons and does not offer material or direction for treatment.

Electrophoresis of Proteins and the Chemistry of Cell Surfaces. By Harold A. Abramson, Assistant Professor of Physiology, College of Physicians and Surgeons, Columbia University, New York; Laurence S. Meyer, Assistant Professor of Botany, University of Minnesota, Minneapolis; and Manuel H. Gorin, Chemical Research Supervisor, Field Research Department, Magnolia Petroleum Company, Dallas. Cloth. Price \$6. 1p. 311 with 153 illustrations. New York: Reinhold Publishing Corporation. 1942.

The application of physicochemical methods to the study of proteins has extended our knowledge of this important class of substances enormously. Of all such methods devised and improved in recent years, electrophoretic methods have proved to be among the most useful. These methods make possible not only a study of the behavior of proteins in solution and at surfaces but also the isolation of individual proteins from complex natural mixtures. In this book the authors have attempted to cover this important field in a fairly complete form. The first six chapters deal with the theoretical and mathematical problems involved in studies of the migration of charged particles in electrical fields together with descriptions of important experimental methods devised for such studies. Later chapters deal with electrophoretic studies of such systems as serum and plasma, antigens and antibodies, enzymes and hormones, protein mixtures, latex, surfaces and finally, the surface chemistry of cells. This book is designed for investigators in diverse fields as physics, chemistry, biology and medicine. It should prove extremely valuable to all students wishing to acquire the necessary background for following the developments in this fruitful field.

The Interaction of Drugs and Cell Catalysts. By Frederick Bernheim Ph.D. Associate Professor of Physiology and Pharmacology, Duke University School of Medicine, Durham, North Carolina. Paper. Price \$2.50. 1p. 80 with 9 illustrations. Minneapolis: Burgess Publishing Company. 1942.

One of the defects in this work the author frankly admits in the preface, namely that "only the pharmacological effects are described that are pertinent to the particular enzyme action under consideration." If a reader failed to observe that statement, the textual discussion might be a little misleading. Part I includes drugs that affect enzyme activity. About half of this part is devoted to the group that modify the action of cholinesterase, the remainder to drugs affecting other enzymes. Each separate subsection carries a bibliography. In the first group are physostigmine, morphine, strychnine, curare and methylene blue. In the second are cyanide, selenium, arsenic, copper, sulfanilamide and salicylate. Part II includes drugs that are acted on by certain enzymes, such as acetanilid, histamine, atropine, acetyl derivatives of morphine, epinephrine and alcohol. The detailed nature of the discussion does not permit of abstracting. The discussion is clear and terse. The subject matter is derived entirely from authentic literature. The author has brought together a great amount of valuable related material not readily assembled from any other source. This makes the monograph a valuable source book.

Preliminary Report on Children's Reactions to the War Including a Critical Survey of the Literature. By J. Louise Despert M.D. Paper. Pp. 102. New York: New York Hospital and the Department of Psychiatry, Cornell University Medical College. 1942.

An excellent review of the literature on children's reactions to war is presented. The method of study utilized is one previously reported in studies of anxiety and fear reactions in normal young children. The present investigation is based on studies of children known to the writer, on records of children previously in attendance at a nursery school and the use of questionnaires sent to parents of children who had previously been instructed in the purpose of the study. Where anxieties in relation to the war were reported or observed invariably the child had previously presented an anxiety problem. Manifestations of anxiety were varied. Fearfulness at night, specific fears of injury and direct fear of blackouts are among the reactions noted. Well-adjusted children tend to express confidence in the outcome of the war. The author states that very young children are not affected by the war; their comments indicating that the words they use bearing on war do not have the emotional content for them that they have for the older

children. The author briefly discusses the protective mechanisms that enable children to cope with the anxiety. Abreaction through play is almost universally noted. She emphasizes the tendency of children to "do something about it," either in phantasy or in activity of defense value. Children who have evidenced anxiety with compulsive tendencies have been able to cope less readily with their anxiety about the war than have those children who, though anxious, were overtly aggressive in their behavior. She adds that while all children showing anxiety in relation to the war had previously presented a problem of anxiety the reverse does not hold. The author concludes from her survey of the literature that the evils of evacuation, as carried out, would appear to be worse than the effects of bombings. The main difficulty is dependent on the separation of children from their parents. Suggestions are made for the further study of the effects of war strain on children.

A Manual for the Differential Diagnosis of Oral Lesions. By Joseph I. Berner. DDS, MS, Major Dental Corps, U. S. Army, Washington. D. C. Cloth. Price \$4. Pp. 228 with 175 illustrations. St. Louis: C. V. Mosby Company, 1942.

Major Berner has successfully attempted a correlation of the clinical and pathologic aspects of the various lesions of the oral tissues. The early chapters deal with indications and technique for biopsy, histology of the skin and mucous membrane, and inflammation. Then follow detailed clinical and histologic discussions of superficial lesions of the oral mucous membrane and adjacent skin, benign and malignant tumors of the mouth and jaws, tumors of odontogenic origin, cysts and miscellaneous diseases of the oral region. The author has drawn on the rich material of the Army Medical Museum and illustrates the text with numerous excellent photomicrographs as well as photographs and x-ray studies of actual cases. No mention is made of an important group of metastatic tumors of the jaws having their primary seat elsewhere in the body. Aside from this omission the book is an excellent presentation of the subject and should be valuable not only to specialists in the oral field but to dermatologists and medical men in general, who frequently have difficulty in finding under one cover accurate information on lesions of the mouth and jaws.

Disability Evaluation. Principles of Treatment of Compensable Injuries. By Earl D. McBride. BS, MD, FACS, Assistant Professor in Orthopedic Surgery, University of Oklahoma School of Medicine, Oklahoma City. Third edition. Cloth. Price \$9. Pp. 631 with 374 illustrations (Art work by Herbert Cheezam). Philadelphia: Montreal & London: J. B. Lippincott Company, 1942.

The present edition of this textbook follows the same arrangement as the first. A brief chapter on the doctor as an expert witness has been added. In addition, the author has presented a table of rating schedules based for the most part on the various state schedules now in effect in the United States. The use of such a composite table, however, is predicated on an arbitrary method of allocating a specified amount to certain factors by which extent of disability is to be measured. These seven factors have been selected from the many variables that comprise what are termed normal states and reactions and cannot themselves be used as a standard, since we do not yet possess any device that will accurately measure the traits involved. How, for instance, can one determine what is a workman's "normal ability to protect himself and others while at work?" The rating of disabilities is so much a social problem that it is a question whether the doctor should not confine himself to an opinion on the clinical findings and leave the economic evaluation to the actuary.

The Principles and Practice of Cardiology. By Crighton Bramwell, MA, MD, FRCP, Professor of Systematic Medicine in the University of Manchester, Manchester, and John T. King, AB, MD, FACP, Associate Professor of Medicine, School of Medicine, Johns Hopkins University, Baltimore. Cloth. Price \$12. Pp. 509 with 204 illustrations. New York & London: Oxford University Press, 1942.

This volume is unique in that the authors have collaborated in writing an Anglo-American textbook of cardiology. It is also unique in its division into general and special cardiology. The first portion of the book, written by Dr. Bramwell of Manchester, England, is devoted to general cardiology and deals with the general problems of heart disease, the history, the physical examination, the disturbances of cardiac function, the

prognosis and the treatment. The second portion of the book, written by Dr. King of Johns Hopkins University, deals with special cardiology. In this section heart disease is considered from the standpoint of etiology. Both authors write from the point of view of the clinician, and they record largely the results of their personal experience. They have done an excellent job of setting forth in a relatively brief volume the essentials of heart disease. It should prove valuable to the student and general practitioner.

The Time of My Life. A Frontier Doctor in Alaska. By Harry Carlos De Vihane. Cloth. Price \$3. Pp. 336. Philadelphia & New York: J. B. Lippincott Company, 1942.

This is the autobiography of a general practitioner of medicine with a long and varied career. The author was an orphan who found himself stranded in New York City at 8 years of age with no home, no friends and no money. He was taken in by a saloon keeper whose credo, it he had one, was loyalty to his friends. After unsuccessful attempts at farming the boy took a freight train for Deadwood, where he hoped to assist his "mink" in the practice of law. In roaming around he met a doctor who had fallen from grace in more ways than one. The orphan remained in the doctor's home, became interested in his medical library and at the age of 19 first had the idea of studying medicine. He matriculated at the Hahnemann Medical College of the Pacific in San Francisco and after an internship applied to the U. S. Bureau of Education for a position in Alaska, where he practiced medicine for many years. He became secretary of the Alaska Board of Medical Examiners and was a delegate from Alaska to the House of Delegates of the American Medical Association during one of its meetings in Dallas. On finally realizing that he was the oldest doctor in Alaska in point of residence but one, the author returned to southern California to spend his remaining years. This book illustrates again that medicine can be practiced well in circumstances that are far more simple than those in the large institutions in populous centers.

Afecciones traumáticas de los meniscos de la rodilla. Por Hector del Lago. Tesis de doctorado. Universidad Nacional de Buenos Aires. Facultad de ciencias médicas. Paper. 1p. 222 with 102 illustrations. Buenos Aires: Adolfo López Imp., 1941.

Much interest attaches to this rather voluminous thesis on traumatic disorders of the knee joint. After reviewing the meniscal anatomy and physiology the author discusses the functional and mechanical alterations of the cartilages under normal and pathologic conditions, the histologic aspects and the meniscal pathologic conditions. About half of the book is devoted to the foregoing discussions. The rest of the work is a clinical consideration of meniscal injuries and diseases. Pneumomorphoradiography of the knee receives a great deal of discussion. Some fifty of the remaining pages are devoted to the treatment of the various meniscal lesions. More than a hundred excellently reproduced illustrations illuminate the text. The pneumomorphoradiograms are particularly interesting and well illustrated. The author considers the use of opaque substances, all of which have been used as less valuable than air or oxygen. Full details of technique are given and at the last a statistical review of sixty-five operations on ruptured cartilages.

The Prospective Mother. A Handbook for Women During Pregnancy. By J. Morris Simons, MD, Professor of Obstetrics and Gynecology, University of California, San Francisco. With a chapter on Care of the Newborn by Philip E. Rothman, MD, Professor of Clinical Pediatrics, University of Southern California, Los Angeles. Fourth edition. Cloth. Price \$2.50. 1p. 271 with 17 illustrations. New York & London: D. Appleton Century Company Incorporated, 1941.

The author has attempted to describe the various changes which occur during pregnancy in the human fetus and the mother. His description of the fetal and maternal changes is not well done. Diagrams and illustrations would have been of inestimably more value than the lengthy descriptions. The major portion of the book concerns the symptoms and signs of pregnancy together with the major and minor complications with a list of the important symptoms and signs. This has been done adequately and the only criticism, a minor one, is that the lists of supplies and clothing could very well have been omitted without in any way detracting from the book. The reviewer recommends the book for pregnant women.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN RECEIVED BY COMPETENT AUTHORITIES. THEY DO NOT NECESSARILY REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

WEIGHT GAIN IN PREGNANCY—CALCIUM, IODIDES AND VITAMIN K IN PREGNANCY

To the Editor—What is the normal monthly gain for the pregnant woman? What preparations of iodine and calcium are best for the pregnant woman? When should vitamin K be given?
M D Pennsylvania

ANSWER—The average weight gain of a normal woman during pregnancy is 9 or 10 Kg. The total weight gain, as well as its distribution during the antepartum period, is of paramount importance. There is little or no gain during the first trimester. Nausea and vomiting or the distaste for food early in the gestation may result in an actual loss of weight. This loss is usually recovered by the end of the first three months. About one third of the total weight gain occurs during the second three months at the rate of 0.25 Kg, or one half pound, a week. During this period much of the accumulation is represented by an increase of the mother's own protein stores. About two thirds of the total weight gain occurs during the last three months of the pregnancy at the average rate of about 0.5 Kg or 1 pound, a week. The baby and its environment grow rapidly during this period and account for much of the increased weight.

Pregnant women should have about 1 Gm of calcium daily in order to cover all fetal requirements. This is ideally supplied by 1 quart of milk a day. Cottage cheese or other milk products are likewise excellent sources of calcium. When calcium is supplied in other forms it is less readily assimilated, and large quantities must be administered. Calcium lactate or calcium gluconate must be given in at least 5 Gm daily doses to provide the minimum requirements.

Iodine is likewise best administered in the diet as sea foods or other iodine rich substances. A very small amount is sufficient to meet the daily requirement. In the Great Lakes region and other localities where goiter is common iodized salt is widely used. In the event that additional iodine is necessary 2 to 3 drops a day of compound solution of iodine may be prescribed.

The role of vitamin K in obstetrics is not clearly defined as yet. Many institutions administer this material prophylactically at the onset of labor. Although this procedure is harmless, its value is still open to question. Vitamin K should be administered subcutaneously to any newborn infant that develops evidence of hemorrhagic disease. Babies who have been subjected to difficult deliveries may possibly benefit from its administration.

CONVULSIONS IN MOTHER AND CHILD AFTER TRANSFUSION

To the Editor—Several days ago a boy aged 8 with acute appendicitis was admitted to the hospital. On operation the appendix was found gangrenous and perforated. The patient was in a state of shock at the conclusion of the operation and 300 cc of citrated whole blood from his mother was administered intravenously. One hour after the transfusion both mother and child had rather severe convulsive seizures lasting about ten minutes. On questioning a history of occasional previous epileptic attacks was elicited from the mother. The child had had no previous attacks. Is it reasonable to suppose that the seizure in the case of the child was produced by some substance in the mother's blood? Have any similar instances been reported?

J W Yast, M D Williamson W Ya

ANSWER—Since no humoral factor has ever been identified in epilepsy, it is doubtful that the convulsive seizures in the child can be ascribed to any substance in the blood which it received from its mother. Many cases of epilepsy are on a constitutional basis, so that the child may have inherited the diathesis from its mother without having previously exhibited any manifestation of the disease. The simultaneous convulsive seizures in mother and child were probably coincidental, though it is possible that the changes in intracranial pressure induced in 1 case by the withdrawal of blood, in the other by its injection, as well as the emotional disturbance incidental to the procedure, may also have played a part. Instances similar to that described in the inquiry have apparently not been encountered previously.

GLOMERULONEPHRITIS

To the Editor—On annual physical examination a miner of iron ore aged 26 was found to have a 4 plus albumin in his urine with many red blood cells. No history of scarlet fever, repeated tonsillitis or other causative factor could be elicited. He asserted that he felt as well as he ever had. The physical examination was entirely normal except for a blood pressure of 142 systolic 88 diastolic. It was later discovered that the same urinary findings had been present on examination in January 1941. Repeated examinations of the urine showed many red blood cells constantly present and occasional showers of hyaline and finely granular casts. A two hour Mosenthal test showed a concentration from 1015 to 1024. Phenolsulfonphthalein excretion was 30 per cent at the end of thirty minutes, 15 per cent at the end of one hour and 5 per cent at the end of two hours for a total of 50 per cent. Nonprotein nitrogen was 27.9 mg, hemoglobin 91 per cent, white blood cells 11,500 with 63 per cent neutrophils, 31 per cent lymphocytes, 1 per cent eosinophils, 4 per cent monocytes and blood sedimentation rate 5 mm in one hour. The blood Kohn reaction was negative. Intravenous pyelograms revealed no abnormalities in the kidneys, kidney pelves or ureters. A chest roentgenogram revealed no pleural, pulmonary or cardiac abnormality. The questions are: in what stage of the disease is this patient at present? In the absence of all symptoms what management would be advised for this patient?
E R Addison M D Crystal Falls Mich

ANSWER—The lines of demarcation between the various stages of glomerulonephritis are not sufficiently sharp to justify a categorical statement from the data available on this case. But precise classification is unnecessary for intelligent management. Obviously the disease is not of long standing or the hemoglobin would have fallen to below the normal level of 91 per cent. Neither is it extremely recent in origin, for there is manifest some rise in the arterial tension and the findings were discovered at least ten months ago. One is most concerned with search for evidence as to the etiologic factors, for effective therapy is predicated on the eradication of active etiologic influences. The mild but distinct leukocytosis is suggestive of an infective origin and further search in the patient's history and physical findings for some active or recently active focus of infection is suggested.

Management may well be divided into three categories: (1) therapy directed against the known and/or suspected etiologic factors, (2) steps taken to reduce the physiologic burden of the injured structures and (3) efforts to maintain the tissue nutrition and respiration as near the optimum as possible. Neglect of any one of this triad of points of attack makes for incomplete and ineffective therapy. Though these three principles are almost universally pertinent, their immediate application must be highly individualized. Therapy directed against caution cannot be suggested until further diagnostic study clarifies the etiologic picture. Infective foci in or about the upper respiratory tract are to be suspected. The frequency of rhinitis and/or pharyngitis may be a significant clue. If toxic heavy metals are suspected as a source of renal injury, urinalysis for such metals is indicated and avoidance of dust or fume exposure becomes of paramount importance.

Rest of the injured structures, the renal parenchymia, is best assured by maintaining a free diuresis through liberal fluid intake. It is less work for the kidneys to secrete a large volume of dilute urine than a small volume of highly concentrated urine. If his work is in deep mining at high environmental temperatures the loss of water through excessive perspiration may be a factor in preventing free water diuresis. It is notable that on the Mosenthal test no really dilute specimen was obtained. Rapid and extensive changes in environmental temperature are to be avoided, chilling is especially detrimental because of the renal vasoconstriction and ischemia consequent thereto. Heavy and prolonged manual labor likewise may affect the renal circulation adversely. A change of occupation may be advisable, but from the data available one cannot state this dogmatically.

Though the third group of therapeutic objectives is of great importance, it is the most commonly neglected aspect of management. With a hemoglobin of 91 per cent and avoidance of those conditions which are conducive to renal vascular constriction, nothing further need or can be done to assure an adequate supply of oxygen for normal tissue respiration by the injured parenchymal cells. The profuse proteinuria, however, is an indication for immediately and emphatically raising the protein intake in the patient's diet. His daily loss of protein should be roughly estimated (the Kingsburg-Clarke sulfosalicylic acid method is the quickest and most satisfactory procedure for quantitation of urinary protein) and more than this amount should be added to the normal daily requirements in the patient's diet. The protein reserves have been depleted by the long and profuse proteinuria, these must be replenished. It is relatively immaterial just what protein food is ingested, the

normal balanced sources of protein such as meat, eggs, milk and cheese are wholly satisfactory. Not infrequently such liberal protein feeding tends to diminish the albuminuria. Alcohol and the "hot" or irritating condiments and spices should be wholly deleted. Tobacco may be allowed in moderation. Periodic reevaluation of the patient's status, particularly as to the blood, the arterial tension and the renal functional capacity, should be carried out at intervals of from three to six months. The renal concentration test is the most sensitive index to early renal functional impairment.

ALLERGY TO HOUSE DUST

To the Editor—Do you know of any unbiased study of so called house dust in its relation to the occurrence of hay fever and asthma in children and particularly as to results obtained after treatment with injections of house dust? Frankly I am extremely skeptical of the whole business and while I do not believe that the rapidly growing group of allergists are actually 'exploiting' still I sometimes wonder if their enthusiasm may not get control of their better judgment. It is entirely possible that in the dust from your house or my house or father's factory or grandpa's chicken coop one might discover certain molds or fungi to which certain individuals might be allergic, but to inject an extract made from the dust from a household vacuum cleaner would seem about as reasonable as to make one from a load of hay and give it to some one who was sensitive to Junco grass. In my practice there is a large proportion of children, and so many of them have been taken to an allergist found sensitive to 'house dust' and given injections that I am a bit bewildered. I cannot honestly show much enthusiasm to the parents as to this procedure and if you have available any opinions on the subject that might make me think there was a bit of benefit to be gained from it by any one but the allergist I should be grateful to be shown the light.

H. G. Bull, M.D., Ithaca, New York

ANSWER—The story of the role of house dust in allergy is a rather complex one and only the highlights can be discussed here. House dust and other dusts have been blamed as the cause in numerous instances of respiratory allergy. These dusts can act in one of three ways: (1) mechanically, (2) chemically and (3) allergically. In many patients various dusts such as house dust, chalk dust and street dust, are of sufficient concentration to produce mechanical irritation of mucous membranes, which can precipitate indirectly an allergic attack in one who is already under the influence of allergic factors. Chemical components in dusts in the home, and more particularly outside the home, may produce similar effects in allergic individuals. In addition to these two properties house dust can without question, act as an allergen. The problem broached in the query is: Are such allergic effects due to a specific identity known as "house dust" or are they due merely to one or more allergens in the home (feathers, cottonseed silk, dog hair, orris root) which are responsible for the allergic qualities?

In 1922 Cooke (*R. A. J. Immunology* 7:147 [March] 1922) first showed evidence supporting the idea that there is a specific allergenic substance in house dust not related necessarily to the specific individual materials in the home. Pratt (*H. N. J. Allergy* 8:60 [Nov.] 1936) and others were able to demonstrate passive transfer of reagins from dust sensitive patients. It was shown by Cohen (*J. Lab. & Clin. Med.* 14:837, 1929) and others that the active "dust" allergen was found mainly in the cotton dust of bedding and furniture rather than in rugs, draperies or new bedding. In trying to trace the mechanism of production of this "dust" allergen, Cohen and his associates (*J. Allergy* 6:517 [Sept.] 1935) found that new cotton linters did not contain this active principle, but the aging of such linters, under any of a number of conditions—exclusion of air, sterilization and exclusion of bacteria and fungi—resulted in a new "dust" antigen. Their experiments suggest that other organic articles, such as feathers or kapok, will produce a similar allergen on aging. In animals a number of experimenters (Cohen, M. B., Cohen, Stanley, and Hawver, *Kenneth J. Allergy* 10:561 [Sept.] 1939; Friedman, H. J., *ibid.* 10:479 [July] 1939; Coulson, E. J., and Stevens, *Henry Proc. Soc. Exper. Biol. & Med.* 40:457 [March] 1939) demonstrated the antigenicity of cotton linters and house dust.

It is common everyday experience with those who see many cases of respiratory allergy that many reactions are obtained to house dust in the absence of reactions to those individual specific allergens which might be present in the home. To say that every person who gives a cutaneous reaction to the dust antigen must react to the dander of some animal or hair article in the home, to feathers, to cottonseed, to orris root or pyrethrum, or to any individual and identifiable allergen is simply to ignore facts. Many such occurrences are common in the practice of any one who is considered unbiased in other matters. In support of these simple clinical observations Hampton and Stull (*J. Allergy* 11:109 [Jan.] 1940) report a series of anti-

genic studies by the Dale test on guinea pigs. Most of the animals sensitized to house dust gave Dale reactions to the latter and some gave reactions to other antigens that might be present in the home, such as dog dander, cat dander and feathers. Desensitization with any of the latter antigens did not desensitize against the house dust antigen. The house dust antigen from homes where the other common inhalant antigens were absent gave as good an antigenic response as the other samples of house dust. They conclude that house dust extract contains an antigen other than that found in the usual inhalants. On the other side of the argument, the work of Albert, Bowman and Walzer (*J. Allergy* 9:392 [May] 1938) must be cited. These workers conclude from clinical and passive transfer studies that, when dust reagins are found, reagins are present also to some other dust producing inhalant, such as wool, feathers, hairs, cottonseed, flaxseed, silk or pyrethrum.

In spite of all these considerations there is good reason to believe that many specimens of dust extract contain chemical and possibly histamine-like irritants which may account for the many wheezing reactions. These clinical impressions are strengthened by the experimental observations of Friedman and also of Coulson and Stevens. It is necessary, therefore, to evaluate a 'house dust' antigen and regard its reactions as significant only if a sufficient number of nonallergic patients fail to give a reaction to it. When this condition is met and allergy to the usual house inhalants can be excluded, one must perforce come to the conclusion that one is dealing with a specific 'house dust' antigen even though practically nothing is known about its nature. The suggestion is made that there is no reason to suppose that this dust antigen which is produced by the aging of organic substances in the home is restricted to the home environment. It is not unreasonable to suppose that similar changes taking place in the organic material outdoors result in an atmospheric antigen which may be widespread and generally distributed. It may perhaps constitute an important source of heretofore unidentified antigen.

Needless to say, the question of treatment must be decided on logical clinical grounds. The criteria for treatment with dust extract should be as follows: 1. The reaction must be shown to be a specific one (not a false irritative reaction). 2. There should be reasonable certainty that the reaction is not due to other antigens which could be more easily procured in pure and potent form such as pollen, feathers, hairs, cottonseed and fungi. 3. Clinical observation should be in conformity with the diagnosis of dust allergy (worse indoors, worse in winter, aggravated by dusting and bed making). 4. If house dust allergy has been reasonably established, dust precautions (dust proof casings for mattress and pillows, simple furniture and the like) should be instituted on the proposition that when the greater source of the dust allergy has been excluded the patient may be able to tolerate the remainder to which he is exposed. 5. Finally, if these procedures have been followed step by step and symptoms still continue, desensitization with dust extract is definitely justified.

TREATMENT OF SYPHILIS IN PATIENT WITH CARCINOMA

To the Editor—In *Queries and Minor Notes* in *The Journal* Nov. 14, 1942, page 872, there appeared under the title "Treatment of Syphilis in Patient with Carcinoma" a query by M.D. New Mexico as to whether subliminal mass would be indicated in such a case and would it be beneficial or what type of antisyphilitic therapy (which would have to be oral) could be given this man. The categorical answer was: At present there are no drugs that can be used orally in the successful treatment of syphilis. This neither answers the question nor indicates any familiarity with the antisyphilitic efficacy of subliminal mass. The correct answer is that subliminal mass is a Council accepted preparation of bismuth for oral use in antisyphilitic treatment; it is clinically successful in all stages of syphilis and there is no good reason to believe that it would not be beneficial in the case referred to. Its usefulness as an antisyphilitic agent is attested by some thirty published reports to date, none of which have denied its efficacy or usefulness. Truth is that subliminal mass (N. N. R.) is the only orally effective bismuth preparation for use in the treatment of syphilis to date and the only one that should be used.

P. J. Hanzlik, M.D., San Francisco

RESUSCITATION OF INFANTS

To the Editor—In *Queries and Minor Notes* in *The Journal* Nov. 21, 1942, Dr. Bundesen's reply to the query on the resuscitation of infants, page 995, did not fully cover the request. On numerous occasions in which infants fail to respond to tracheal catheterization and the milder attempts at resuscitation the cause is revealed at autopsy. This is often cerebral hemorrhage due to prolonged labor or operative delivery by forceps and especially by haste in delivery of breech cases.

John Joseph Gill, M.D., Chicago

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, SEPTEMBER-DECEMBER 1942

Titles have been listed of Abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1932. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THIS JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: 'B,' Bureau of Investigation, 'E,' Editorial, 'C,' Correspondence, 'OS,' Organization Section, 'ab,' abstracts, the star (*) indicates an original article in THIS JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: 'Book Notices,' 'Dentists,' 'Medical Abstracts' and 'Societies' are indexed under these titles at the end of the letters 'B,' 'D,' 'M,' and 'S.' State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

EPITHELIOMA Chorloepithelioma See Chorioepithelioma
of skin of ear x rays and radium for [Drivel] 478—ab
FIBRINOLYTIC See Tuberculosis Pulmonary
EQUILIBRIUM factor in aerial equilibration of talpids [Carson] *7 1309—E
EQUIPMENT See also Apparatus Instruments Medical Supplies
for emergency medical services 209
ERB Goldham's Disease See Myasthenia gravis
ERFECTIOS See Pests
ERGOSTEROL irradiated poisoning [Bachrach] 787—C
ERGOTAMINE tartrate effect on electrocardiogram [Hartwell] 237—ab
ERIODICTY vitamin P 1401—E
ERNESTO PEDRO death 1240
ERUCTION what causes fluence? [Alvarez] *21
ERUPTIONS See also under names of specific diseases as Measles Scarlet Fever
Congenital Bullous See Epidermolysis bullosa
infectious undescribed [Blake] 405—ab
photosensitivity of sulfonamides [Park] 1435
toxic from phenobarbital [Voss] 1062—ab
toxic from sulfathiazole preparations 1169
ERYTHEMA nodosum [Poppel] 1067—ab
nodosum in venereal lymphogranuloma [Hellerström] 798—ab
ERYTHRALGIA See Erythromelalgia
ERYTHEMA See Polycythemia
ERYTHROBLASTOSIS fetal and skeletal changes [Folliis] 316—ab
ERYTHROBLASTS See Anemia erythroblastic familial
ERYTHROCYTES Count See Anemia Pernicious Polycythemia
of cattle 30 different hereditary isoagglutinogens in 536—E
Sedimentation See Blood sedimentation
transfused demonstrated in recipient's blood [Kruppe] 160—ab
transfused fate of [Willenegger] 1437—ab
waste advisable to return to donor of plasma 727
ERYTHROMELALGIA of Head See Cephalalgia
massive edema of feet and ankles of undetermined cause 577
ESCHERICHIA coli succinylsulfathiazole effect on [Folliis] *265
ESOPHAGUS hemorrhage (massive) after liver cirrhosis treatment [Grace] 1163—ab
occluded man fed himself through large gastric fistula stoma [Wolf & Wolf] *670
perforated abscess [Orton] *877
ESTRADIOL dipropionate in prostate cancer [Herbst] *1116
ethinyl oral for menopause symptoms [Watson] 649—ab
experimental fibroids and antifibromatogenic action [Lipschütz] *171
ESTROGENS See also Estradiol
Diethylstilbestrol See Diethylstilbestrol
fibroids induced by [Lipschütz] *171
implanting persistent endometrial bleeding after 575
injections effect on electrical record of ovulation [Langman] 564—ab
pregnancy toxemia relation to [Taylor] *595
prostatic epithelium relation to [Alvey & Henderson] *1100
standardization (Council report) 921
treatment of arthritis 411
treatment of emaciation [Saurer] 485—ab
treatment of gonorrhea vulvovaginitis [Brown] 647—ab
treatment of hypertension angina pectoris vascular disease [Walker] 1251—ab
treatment of prostate cancer [Kearns] 240—ab [Kable] 317—ab [Alvey & Henderson] *1099 [Gutman] *1115 [Herbst] *1116
treatment of senile pruritus [Feldman] 103—ab
ETHANOLAMINE solution treatment of burns [Rothman & others] *803
ETHER See Anesthesia
ETHICS See Medicolegal Abstracts at end of letter M
ETHINYL estradiol oral for menopause symptoms [Watson] 649—ab
ETHYNOID BONE Cushing olfactory meningioma x ray diagnosis [Erikson] 116—ab
fracture treatment [Shea] *747
ETHYL aminobenzoate to relieve itching in trombidiosis (chigger bites) [Sutton] *26
chloride freezing to relieve pain and loss of movement [Henry] 1206—ab
chloride spray in soft tissue injury [McIntosh] 1256—ab
ETHYLENE disulphonate as asthma cure 342—E
glycol (Prestone antifreeze) added to wine death from drinking 575
treatment of fruits effect on nutritive value, [Hohman] *837
